Abstract

SNOPT is a general-purpose system for constrained optimization. It minimizes a linear or nonlinear function subject to bounds on the variables and sparse linear or nonlinear constraints. It is suitable for large-scale linear and quadratic programming and for linearly constrained optimization, as well as for general nonlinear programs.

SNOPT finds solutions that are *locally optimal*, and ideally any nonlinear functions should be smooth and users should provide gradients. It is often more widely useful. For example, local optima are often global solutions, and discontinuities in the function gradients can often be tolerated if they are not too close to an optimum. Unknown gradients are estimated by finite differences.

SNOPT uses a sequential quadratic programming (SQP) algorithm. Search directions are obtained from QP subproblems that minimize a quadratic model of the Lagrangian function subject to linearized constraints. An augmented Lagrangian merit function is reduced along each search direction to ensure convergence from any starting point.

On large problems, SNOPT is most efficient if only some of the variables enter nonlinearly, or if many constraints (including simple bounds) are active. SNOPT requires relatively few evaluations of the problem functions. Hence it is especially effective if the objective or constraint functions (and their gradients) are expensive to evaluate.

The source code for SNOPT is suitable for any machine with a Fortran compiler or the f2c translator. SNOPT may be called from a driver program (typically in Fortran, C or MATLAB). It can also be used as a stand-alone package, reading data in the MPS format used by commercial mathematical programming systems.

Keywords: Nonlinear programming, constrained optimization, nonlinear constraints, SQP methods, limited-storage quasi-Newton updates, Fortran software.

1. Introduction

SNOPT is a general-purpose system for constrained optimization. It minimizes a linear or nonlinear function subject to bounds on the variables and sparse linear or nonlinear constraints. It is suitable for large-scale linear and quadratic programming and for linearly constrained optimization, as well as for general nonlinear programs of the form

SparseNP
$$\min_x f_0(x)$$

$$\text{subject to } l \leq \begin{pmatrix} x \\ f(x) \\ A_L x \end{pmatrix} \leq u,$$

where l and u are constant lower and upper bounds, $f_0(x)$ is a smooth scalar objective function, A_L is a sparse matrix, and f(x) is a vector of smooth nonlinear constraint functions $\{f_i(x)\}$. An optional parameter maximize may specify that $f_0(x)$ should be maximized instead of minimized.

Ideally, the first derivatives (gradients) of $f_0(x)$ and $f_i(x)$ should be known and coded by the user. If only some of the gradients are known, SNOPT will estimate the missing ones with finite differences.

Note that upper and lower bounds are specified for all variables and constraints. This form allows full generality in specifying various types of constraint. Special values are used to indicate absent bounds ($l_j = -\infty$ or $u_j = +\infty$ for appropriate j). Free variables and free constraints ("free rows") are ones that have both bounds infinite. Fixed variables and equality constraints have $l_j = u_j$.

1.1. Problem types

If $f_0(x)$ is linear and f(x) is absent, SparseNP is a *linear program* (LP) and SNOPT applies the primal simplex method [2]. Sparse basis factors are maintained by LUSOL [10] as in MINOS [16].

If only the objective is nonlinear, the problem is *linearly constrained* (LC) and tends to solve more easily than the general case with nonlinear constraints (NC). For both cases, SNOPT applies a sparse sequential quadratic programming (SQP) method [8], using limited-memory quasi-Newton approximations to the Hessian of the Lagrangian. The merit function for steplength control is an augmented Lagrangian, as in the dense SQP solver NPSOL [9, 12].

In general, SNOPT requires less matrix computation than NPSOL and fewer evaluations of the functions than the nonlinear algorithms in MINOS [14, 15]. It is suitable for nonlinear problems with thousands of constraints and variables, and is efficient if many constraints and bounds are active at a solution. (Thus, ideally there should not be thousands of degrees of freedom.)

1.2. Implementation

SNOPT is implemented as a set of callable Fortran subroutines. The source code is compatible with all known Fortran 77, 90 and 95 compilers, and can be converted to C code by the f2c translator [4].

All routines in SNOPT are intended to be re-entrant (as long as the compiler allocates local variables dynamically). Hence they may be used in a parallel or multi-threaded environment. They may also be called recursively.

1.3. The SNOPT interfaces

SNOPT contains several *interfaces* between the user and the underlying solver, allowing problems to be specified in various formats.

New users are encouraged to use the snOptA interface. This allows linear and nonlinear constraints and variables to be entered in *arbitrary order*, and allows all nonlinear functions to be defined in one user routine. It may also be used with SnadiOpt [7], which provides gradients by *automatic differentiation* of the problem functions.

For efficiency reasons, the solver routines require nonlinear variables and constraints to come before linear variables and constraints, and they treat nonlinear objective functions separately from nonlinear constraints. snOptB (the *basic* interface) imposes these distinctions and was used by all versions of SNOPT prior to Version 6.

In some applications, the objective and constraint functions share data and computation. The snOptC interface allows the functions to be *combined* in one user routine.

Finally, npOpt is an interface that accepts problem data written in the same format as the dense SQP code NPSOL. It permits NPSOL users to upgrade with minimum effort.

A summary of the SNOPT interfaces follows:

snOptA (Section 3) is recommended for new users of SNOPT. The variables and constraints may be coded in any order. Nonlinear objective and constraint functions are defined by one user routine. May use SnadiOpt to compute gradients.

snOptB (Section 4) is the basic interface to the underlying solver. Nonlinear constraints and variables must appear first. A nonlinear objective is defined separately from any nonlinear constraints.

snOptC (Section 5) is the same as snOptB except the user combines the nonlinear objective
and constraints into one routine.

npOpt (Section 6) accepts the same problem format as NPSOL. It is intended for moderate-sized dense problems (as is NPSOL!).

1.4. Files

Every SNOPT interface reads or creates some of the following files:

PRINT file (Section 8) is a detailed iteration log with error messages and perhaps listings of the options and the final solution.

SUMMARY file (Section 8.9) is a brief iteration log with error messages and the final solution status. Intended for screen output in an interactive environment.

SPECS file (Section 7) is a set of run-time options, input by snSpec.

SOLUTION file (Sections 8.7–8.8) keeps a separate copy of the final solution listing.

BASIS files (Section 9) allow restarts.

Unit numbers for the PRINT, SUMMARY and SPECS files are defined by input parameters to snInit and snSpec.

1.5. Overview of the package

SNOPT is normally accessed via a sequence of subroutine calls. For example, the interface snOptA is invoked by the statements

```
call snInit( iPrint, iSumm, ... )
call snSpec( iSpecs, ... )
call snoptA( Start, nF, n, ... )
```

where snSpec reads a file of run-time options (if any). Also, individual run-time options may be "hard-wired" by calls to snSet, snSeti and snSetr.

1.6. Subroutine snInit

Subroutine snInit must be called before any other SNOPT routine. It defines the PRINT and SUMMARY files, prints a title on both files, and sets all user options to be undefined. (Each SNOPT interface will later check the options and set undefined ones to default values.)

```
subroutine snInit
& ( iPrint, iSumm, cw, lencw, iw, leniw, rw, lenrw )
integer
& iPrint, iSumm, lencw, leniw, lenrw, iw(leniw)
character
& cw(lencw)*8
double precision
& rw(lenrw)
```

On entry:

iPrint defines a unit number for the PRINT file. Typically iPrint = 9.

On some systems, the file may need to be opened before snInit is called. If $iPrint \leq 0$, there will be no PRINT file output.

iSumm defines a unit number for the SUMMARY file. Typically iSumm = 6. (In an interactive environment, this usually denotes the screen.)

On some systems, the file may need to be opened before \mathtt{snInit} is called. If $\mathtt{iSumm} < 0$, there will be no SUMMARY file output.

cw(lencw), iw(leniw), rw(lenrw) must be the same arrays that are passed to other SNOPT routines. They must all have length 500 or more.

On exit:

Some elements of cw, iw, rw are given values to indicate that most optional parameters are undefined.

2. Description of the SQP method

Here we summarize the main features of the SQP algorithm used in SNOPT and introduce some terminology used in the description of the subroutine and its arguments. The SQP algorithm is fully described by Gill, Murray and Saunders [8].

2.1. Constraints and slack variables

The upper and lower bounds on the m components of f(x) and $A_L x$ are said to define the general constraints of the problem. SNOPT converts the general constraints to equalities by introducing a set of slack variables $s = (s_1, s_2, \ldots, s_m)^T$. For example, the linear constraint $5 \le 2x_1 + 3x_2 \le +\infty$ is replaced by $2x_1 + 3x_2 - s_1 = 0$ together with the bounded slack $5 \le s_1 \le +\infty$. SparseNP can therefore be written in the equivalent form

minimize
$$f_0(x)$$

subject to $\begin{pmatrix} f(x) \\ A_L x \end{pmatrix} - s = 0, \quad l \le \begin{pmatrix} x \\ s \end{pmatrix} \le u.$

The general constraints become the equalities $f(x) - s_N = 0$ and $A_L x - s_L = 0$, where s_L and s_N are known as the *linear* and *nonlinear* slacks.

2.2. Major iterations

The basic structure of the SQP algorithm involves major and minor iterations. The major iterations generate a sequence of iterates $\{x_k\}$ that satisfy the linear constraints and converge to a point that satisfies the first-order conditions for optimality. At each iterate a QP subproblem is used to generate a search direction towards the next iterate x_{k+1} . The constraints of the subproblem are formed from the linear constraints $A_L x - s_L = 0$ and the nonlinear constraint linearization

$$f(x_k) + f'(x_k)(x - x_k) - s_N = 0,$$

where $f'(x_k)$ denotes the Jacobian matrix, whose elements are the first derivatives of f(x) evaluated at x_k . The QP constraints therefore comprise the m linear constraints

$$f'(x_k)x - s_N = -f(x_k) + f'(x_k)x_k,$$

$$A_L x - s_L = 0,$$

where x and s are bounded above and below by u and l as before. If the $m \times n$ matrix A and m-vector b are defined as

$$A = \begin{pmatrix} f'(x_k) \\ A_L \end{pmatrix}$$
 and $b = \begin{pmatrix} -f(x_k) + f'(x_k)x_k \\ 0 \end{pmatrix}$,

then the QP subproblem can be written as

minimize
$$q(x)$$
 subject to $Ax - s = b$, $l \le \begin{pmatrix} x \\ s \end{pmatrix} \le u$, (2.1)

where q(x) is a quadratic approximation to a modified Lagrangian function [8].

2.3. Minor iterations

Solving the QP subproblem is itself an iterative procedure. The iterations of the QP solver are the *minor* iterations of the SQP method. At each minor iteration, the constraints Ax - s = b are (conceptually) partitioned into the form

$$Bx_{B} + Sx_{S} + Nx_{N} = b,$$

where the basis matrix B is square and nonsingular. The elements of x_B , x_S and x_N are called the basic, superbasic and nonbasic variables respectively; they are a permutation of the elements of x and s. At a QP solution, the basic and superbasic variables will lie somewhere between their bounds, while the nonbasic variables will normally be equal to one of their bounds. At each iteration, x_S is regarded as a set of independent variables that are free to move in any desired direction, namely one that will improve the value of the QP objective (or the sum of infeasibilities). The basic variables are then adjusted in order to ensure that (x,s) continues to satisfy Ax - s = b. The number of superbasic variables (n_S, say) therefore indicates the number of degrees of freedom remaining after the constraints have been satisfied. In broad terms, n_S is a measure of how nonlinear the problem is. In particular, n_S will always be zero for LP problems.

If it appears that no improvement can be made with the current definition of B, S and N, a nonbasic variable is selected to be added to S, and the process is repeated with the value of n_S increased by one. At all stages, if a basic or superbasic variables encounters one of its bounds, the variables is made nonbasic and the value of n_S is decreased by one.

Associated with each of the m equality constraints Ax - s = b are the dual variables π . Similarly, each variable in (x,s) has an associated reduced gradient d_j . The reduced gradients for the variables x are the quantities $g - A^T \pi$, where g is the gradient of the QP objective, and the reduced gradients for the slacks are the dual variables π . The QP subproblem is optimal if $d_j \geq 0$ for all nonbasic variables at their lower bounds, $d_j \leq 0$ for all nonbasic variables at their upper bounds, and $d_j = 0$ for other variables, including superbasics. In practice, an approximate QP solution $(\widehat{x}_k, \widehat{s}_k, \widehat{\pi}_k)$ is found by relaxing these conditions.

2.4. The merit function

After a QP subproblem has been solved, new estimates of the SparseNP solution are computed using a line search on the augmented Lagrangian merit function

$$\mathcal{M}(x, s, \pi) = f_0(x) - \pi^T (f(x) - s_N) + \frac{1}{2} (f(x) - s_N)^T D(f(x) - s_N), \tag{2.2}$$

where D is a diagonal matrix of penalty parameters $(D_{ii} \geq 0)$. If (x_k, s_k, π_k) denotes the current solution estimate and $(\hat{x}_k, \hat{s}_k, \hat{\pi}_k)$ denotes the QP solution, the line search determines a step α_k $(0 < \alpha_k \leq 1)$ such that the new point

$$\begin{pmatrix} x_{k+1} \\ s_{k+1} \\ \pi_{k+1} \end{pmatrix} = \begin{pmatrix} x_k \\ s_k \\ \pi_k \end{pmatrix} + \alpha_k \begin{pmatrix} \widehat{x}_k - x_k \\ \widehat{s}_k - s_k \\ \widehat{\pi}_k - \pi_k \end{pmatrix}$$
(2.3)

gives a sufficient decrease in the merit function (2.2). When necessary, the penalties in D are increased by the minimum-norm perturbation that ensures descent for \mathcal{M} [12]. As in NPSOL, s_N is adjusted to minimize the merit function as a function of s prior to the solution of the QP subproblem. For more details, see [9, 3].

2.5. Treatment of constraint infeasibilities

SNOPT makes explicit allowance for infeasible constraints. First, infeasible *linear* constraints are detected by solving the linear program

where e is a vector of ones, and the nonlinear constraint bounds are temporarily excluded from l and u. This is equivalent to minimizing the sum of the general linear constraint violations subject to the bounds on x. (The sum is the ℓ_1 -norm of the linear constraint violations. In the linear programming literature, the approach is called *elastic programming*.)

The linear constraints are infeasible if the optimal solution of FLP has $v \neq 0$ or $w \neq 0$. SNOPT then terminates without computing the nonlinear functions.

Otherwise, all subsequent iterates satisfy the linear constraints. (Such a strategy allows linear constraints to be used to define a region in which the functions can be safely evaluated.) SNOPT proceeds to solve SparseNP as given, using search directions obtained from the sequence of QP subproblems (2.1).

If a QP subproblem proves to be infeasible or unbounded (or if the dual variables π for the nonlinear constraints become large), SNOPT enters "elastic" mode and thereafter solves the problem

NP(
$$\gamma$$
) minimize $f_0(x) + \gamma e^T(v + w)$
subject to $l \le \begin{pmatrix} x \\ f(x) - v + w \\ A_L x \end{pmatrix} \le u, \quad v \ge 0, \quad w \ge 0,$

where γ is a nonnegative parameter (the *elastic weight*), and $f_0(x) + \gamma e^T(v + w)$ is called a *composite objective* (the ℓ_1 penalty function for the nonlinear constraints).

The value of γ may increase automatically by multiples of 10 if the optimal v and w continue to be nonzero. If γ is sufficiently large, this is equivalent to minimizing the sum of the nonlinear constraint violations subject to the linear constraints and bounds. A similar ℓ_1 formulation of SparseNP is fundamental to the S ℓ_1 QP algorithm of Fletcher [5]. See also Conn [1].

The initial value of γ is controlled by the optional parameters Elastic mode and Elastic weight (p. 74).

3. The snOptA interface

The snOptA interface accepts a format that allows the constraints and variables to be defined in any order. The optimization problem is assumed to be in the form

NPA minimize
$$F_{obj}(x)$$
 subject to $l_x \le x \le u_x$, $l_F \le F(x) \le u_F$,

where the upper and lower bounds are constant, F(x) is a vector of smooth linear and nonlinear constraint functions $\{F_i(x)\}$, and $F_{obj}(x)$ is one of the components of F to be minimized, as specified by the input parameter \mathtt{ObjRow} . (The option maximize specifies that $F_{obj}(x)$ should be maximized instead of minimized.) \mathtt{snOptA} reorders the variables and constraints so that the problem is in the form SparseNP.

Ideally, the first derivatives (gradients) of F_i should be known and coded by the user. If only some gradients are known, snOptA estimates the missing ones with finite differences.

Note that upper and lower bounds are specified for all variables and functions. This form allows full generality in specifying various types of constraint. Special values are used to indicate absent bounds ($l_j = -\infty$ or $u_j = +\infty$ for appropriate j). Free variables and free constraints ("free rows") are ones that have both bounds infinite. Fixed variables and equality constraints have $l_j = u_j$.

In general, the components of F are *structured* in the sense that they are formed from sums of linear and nonlinear functions of just some of the variables. This structure can be exploited by snOptA (see Section 3.3).

3.1. Subroutines associated with snOptA

snOptA is accessed via the following routines:

```
snInit (Section 1.6) must be called before any other snOptA routines.
snSpec (Section 7.3) may be called to input a SPECS file (a list of run-time options).
snSet, snSeti, snSetr (Section 7.4) may be called to specify a single option.
snGet, snGetc, snGeti, snGetr (Section 7.5) may be called to obtain an option's current value.
snJac (Section 3.5) may be called to find the coordinate stucture of the Jacobian.
usrfun (Section 3.6) is supplied by the user and called by snOptA to define the functions F<sub>i</sub>(x) and ideally their gradients.
snOptA (Section 3.4) is the main solver.
snMemA (Section 3.8) computes the size of the workspace arrays cw, iw, rw required for given problem dimensions. Intended for Fortran 90 and C drivers that reallocate workspace if necessary.
```

The user routine usrfun has a fixed parameter list but may have any convenient name. It is passed to snOptA as a parameter.

3.2. Getting Started

Consider the following nonlinear optimization problem with two variables $x = (x_1, x_2)$ and three inequality constraints:

minimize
$$x_2$$

subject to $x_1^2 + 4x_2^2 \le 4$, $(x_1 - 2)^2 + x_2^2 \le 5$, $x_1 \ge 0$. (3.1)

In the format of problem NPA, we have $l_x \le x \le u_x$ and $l_F \le F(x) \le u_F$ as follows:

$$l_x = \begin{pmatrix} 0 \\ -\infty \end{pmatrix} \le \begin{pmatrix} x_1 \\ x_2 \end{pmatrix} \le \begin{pmatrix} +\infty \\ +\infty \end{pmatrix} = u_x,$$

$$l_F = \begin{pmatrix} -\infty \\ -\infty \\ -\infty \end{pmatrix} \le \begin{pmatrix} x_2 \\ x_1^2 + 4x_2^2 \\ (x_1 - 2)^2 + x_2^2 \end{pmatrix} \le \begin{pmatrix} +\infty \\ 4 \\ 5 \end{pmatrix} = u_F.$$

Let G(x) be the Jacobian matrix of partial derivatives, so that $G_{ij}(x) = \partial F_i(x)/\partial x_j$ gives the gradients of $F_i(x)$ as the *i*th row of G:

$$F(x) = \begin{pmatrix} x_2 \\ x_1^2 + 4x_2^2 \\ (x_1 - 2)^2 + x_2^2 \end{pmatrix} \quad \text{and} \quad G(x) = \begin{pmatrix} 0 & 1 \\ 2x_1 & 8x_2 \\ 2(x_1 - 2) & 2x_2 \end{pmatrix}.$$

Now we must provide snOptA the following information:

- 1. The index Objrow of the objective row. Here, ObjRow = 1.
- 2. The upper and lower bounds on x. The vectors l_x and u_x are input as arrays:

infBnd = 1.0d+20 xlow(1) = 0.0 xlow(2) = -infBnd xupp(1) = infBnd xupp(2) = infBnd

where infBnd represents "infinity". It must be at least as large as the Infinite Bound size (default value 10^{20}).

3. The upper and lower bounds on F(x). The vectors l_F and u_F are also in arrays:

Flow(1) = -infBnd Flow(2) = -infBnd Flow(3) = -infBnd Fupp(1) = infBnd Fupp(2) = 4.0 Fupp(3) = 5.0

Note that the objective row must have infinite bounds to make it a "free" row.

4. A subroutine usrfun that computes F(x). For this example, usrfun would contain the assignments

```
F(1) = x(2)! The objective row F(2) = x(1)**2 + 4.0*x(2)**2 F(3) = (x(1) - 2.0)**2 + x(2)**2
```

5. As many elements of G(x) as possible. Ideally, Derivative option 1 should be specified and subroutine usrfun should compute all derivatives of F(x). Elements that are identically zero may be omitted.

Here, usrfun could include the following additional assignments. They compute all G_{ij} row-wise, excluding $G_{11} \equiv 0$:

The elements of G may be stored in any order (row-wise, column-wise, or more randomly). The ordering implies a list of coordinates $\{(i,j)\}$, in this case

$$(1,2)$$
 $(2,1)$ $(2,2)$ $(3,1)$ $(3,2)$.

This list must match the integer arrays iffun and jGvar below.

If Derivative option 0 is specified, some or all of the gradient elements need not be assigned values in G. snOptA will estimate them by finite differences.

6. The pattern of nonzero elements of the Jacobian G. This is a list of coordinates $\{(i,j)\}$ of the nonzero elements G_{ij} , held in two integer arrays. If i = iGfun(k) and j = jGvar(k), then G(k) holds G_{ij} . In the example, the program calling snOptA would include the following:

```
iGfun(1) = 1
               ! row coordinate of G(1) = 1.0
jGvar(1) = 2
               ! col coordinate of G(1)
               ! row coordinate of G(2) = 2.0 * x(1)
iGfun(2) = 2
jGvar(2) = 1
               ! col coordinate of G(2)
iGfun(3) = 2
               ! row coordinate of G(3) = 8.0 * x(2)
jGvar(3) = 2
               ! col coordinate of G(3)
iGfun(4) = 3
               ! row coordinate of G(4) = 2.0*(x(1) - 2.0)
jGvar(4) = 1
               ! col coordinate of G(4)
               ! row coordinate of G(5) = 2.0 \times x(2)
iGfun(5) = 3
jGvar(5) = 2
               ! col coordinate of G(5)
```

If Derivative option 0 is specified, iGfun and jGvar may be defined *automatically* by calling subroutine snJac (p. 20).

3.3. Exploiting problem structure

In many cases, the vector F(x) is a sum of linear and nonlinear functions. snOptA allows these terms to be specified separately, so that the linear part is defined just once by the input arguments iAfun, jAvar, and A. Only the nonlinear part is recomputed at each x.

Suppose that each component of F(x) is of the form

$$F_i(x) = f_i(x) + \sum_{j=1}^{n} A_{ij} x_j,$$

where $f_i(x)$ is a nonlinear function (possibly zero) and the elements A_{ij} are constant. The $nF \times n$ Jacobian of F(x) is the sum of two sparse matrices of the same size: F'(x) = G(x) + A, where G(x) = f'(x) and A is the matrix with elements $\{A_{ij}\}$. The two matrices must be non-overlapping in the sense that every element of the Jacobian F'(x) = G(x) + A is an element of G(x) or an element of A, but not both.

For example, the function

$$F(x) = \begin{pmatrix} 3x_1 + e^{x_2}x_4 + x_2^2 + 4x_4 - x_3 + x_5 \\ x_2 + x_3^2 + \sin x_4 - 3x_5 \\ x_1 - x_3 \end{pmatrix}$$

can be written as

$$F(x) = f(x) + Ax = \begin{pmatrix} e^{x_2}x_4 + x_2^2 + 4x_4 \\ x_3^2 + \sin x_4 \\ 0 \end{pmatrix} + \begin{pmatrix} 3x_1 - x_3 + x_5 \\ x_2 - 3x_5 \\ x_1 - x_3 \end{pmatrix},$$

in which case

$$F'(x) = \begin{pmatrix} 3 & e^{x_2}x_4 + 2x_2 & -1 & e^{x_2} + 4 & 1\\ 0 & 1 & 2x_3 & \cos x_4 & -3\\ 1 & 0 & 0 & 0 & 0 \end{pmatrix}$$

can be written as F'(x) = f'(x) + A = G(x) + A, where

$$G(x) = \begin{pmatrix} 0 & e^{x_2}x_4 + 2x_2 & 0 & e^{x_2} + 4 & 0 \\ 0 & 0 & 2x_3 & \cos x_4 & 0 \\ 0 & 0 & 0 & 0 & 0 \end{pmatrix}, \quad A = \begin{pmatrix} 3 & 0 & -1 & 0 & 1 \\ 0 & 1 & 0 & 0 & -3 \\ 1 & 0 & -1 & 0 & 0 \end{pmatrix}.$$

The nonzero elements of A and G are provided to snOptA in coordinate form. The elements of A are entered as triples (i, j, A_{ij}) in the arrays iAfun, jAvar, A. The sparsity pattern of G is entered as pairs (i, j) in the arrays iGfun, jGvar. The corresponding entries G_{ij} (any that are known) are assigned to appropriate array elements G(k) in the user's subroutine usrfun.

The elements of A and G may be stored in any order. Duplicate entries are ignored. As mentioned, iffun and jGvar may be defined automatically by subroutine snJac (p. 20) when Derivative option 0 is specified and usrfun does not provide any gradients.

3.4. Subroutine snOptA

Problem NPA is solved by a call to subroutine snOptA, whose parameters are defined here. Note that most machines use double precision declarations as shown, but some machines use real. The same applies to the function routine usrfun and all other routines.

```
subroutine snOptA
    (Start, nF, n, nxname, nFname,
&
      ObjAdd, ObjRow, Prob, usrfun,
&
      iAfun, jAvar, lenA, neA, A,
&
      iGfun, jGvar, lenG, neG,
&
      xlow, xupp, xnames, Flow, Fupp, Fnames,
      x, xstate, xmul, F, Fstate, Fmul,
&
&
      INFO, mincw, miniw, minrw,
&
      nS, nInf, sInf,
      cu, lencu, iu, leniu, ru, lenru,
Хr.
      cw, lencw, iw, leniw, rw, lenrw)
external
&
      usrfun
integer
      INFO, lenA, lencu, lencw, lenG, leniu, leniw, lenru, lenrw,
&
&
      mincw, miniw, minrw, n, neA, neG, nF, nFname, nInf, nS,
&
      nxname, ObjRow, Start, iAfun(lenA), iGfun(lenG), iu(leniu),
      iw(leniw), jAvar(lenA), jGvar(lenG), xstate(n), Fstate(nF)
 double precision
      ObjAdd, sInf, A(lenA), F(nF), Fmul(nF), Flow(nF), Fupp(nF),
&
&
      ru(lenru), rw(lenrw), x(n), xlow(n), xmul(n), xupp(n)
 character
      Prob*8, cu(lencu)*8, cw(lencw)*8,
&
      Fnames(nFname)*8, xnames(nxname)*8
```

On entry:

Start is an integer that specifies how a starting basis (and certain other items) are to be obtained.

Start = 0 (Cold start) requests that the CRASH procedure be used to choose an initial basis, unless a basis file is provided via OLD BASIS, INSERT or LOAD in the SPECS file.

Start = 1 is the same as start = 0 but is more meaningful when a basis file is given.

Start = 2 (Warm start) means that a basis is already defined in xstate and Fstate (probably from an earlier call).

nF is the number of problem functions in F(x), including the objective function (if any) and the linear and nonlinear constraints. Simple upper and lower bounds on x can be defined using the parameters xLow and xUpp defined below and should not be included in F. (nF > 0)

This is the dimension of the problem vector F.

Since F includes the objective (if any) and all the general linear and nonlinear constraints, F must include at least one row for the problem to be meaningful.

- n is n, the number of variables. This is the number of columns of G and A. (n > 0)
- iAfun(lenA), jAvar(lenA), A(lenA) define the coordinates (i, j) and values A_{ij} of the nonzero elements of the linear part A of the function F(x) = f(x) + Ax.

In particular, the neA triples (iAfun(k), jAvar(k), A(k)), define the row and column indices i = iAfun(k) and j = jAvar(k) of the element $A_{ij} = A(k)$.

The coordinates may define the elements of A in any order.

- lenA is the dimension of the coordinate arrays iAfun, jAvar and A that hold (i, j, A_{ij}) . (lenA ≥ 1)
- neA is the number of nonzeros in A such that F(x) = f(x) + Ax. (neA ≥ 0)
- iGfun(leng), jGvar(leng) define the coordinates (i,j) of the nonzero elements of G, the nonlinear part of the derivatives J(x) = G(x) + A of the function F(x) = f(x) + Ax. The actual elements of G are assigned in the subroutine usrfun.

The coordinates can define the elements of G in any order. However, subroutine usrfun must define the actual elements of G in the exactly the same order as defined by the coordinates (iGfun, jGvar).

- lenG is the dimension of the coordinate arrays iffun and jGvar that define the varying Jacobian elements (i, j, G_{ij}) . (lenG ≥ 1)
- neG is the number of nonzero entries in G. ($neG \ge 0$)
- nxname, nFname give the number of variable and constraint names provided in the character arrays xname and Fname. If nxname = 1 and nFname = 1, no variable and constraint names are provided. Generic names will be used in the printed solution. Otherwise, nxname and nFname must be given the values nxname = n and nFname = nF, and all names must be provided.
- ObjAdd is a constant that will be added to the objective row F(Objrow) for printing purposes. Typically ObjAdd = 0.0d+0.
- ObjRow says which row of F is to act as the objective function. If there is no such vector, $\mathsf{ObjRow} = 0$ and snOptA will attempt to find a point such that $l_F \leq F(x) \leq u_F$ and $l_x \leq x \leq u_x$. $(0 \leq \mathsf{ObjRow} \leq \mathsf{nF})$
- Prob is an 8-character name for the problem. Prob is used in the printed solution and in some routines that output BASIS files. A blank name may be used.
- usrfun (Section 3.6) is the name of a subroutine that calculates the vector of problem functions F(x) and (optionally) its Jacobian F'(x) for a given vector x. usrfun must be declared external in the routine that calls snOptA.
- xlow(n), xupp(n) contain the lower and upper bounds l_x and u_x on the variables x.

To specify a non-existent lower bound $[l_x]_j = -\infty$, set $\mathtt{xlow}(j) \leq -\mathtt{infBnd}$, where infBnd is the Infinite Bound size, whose default value is 10^{20} . To specify a non-existent upper bound $[u_x]_j = \infty$, set $\mathtt{xupp}(j) \geq \mathtt{infBnd}$.

To fix the jth variable (say $x_j = \beta$, where $|\beta| < \text{infBnd}$), set $xlow(j) = xupp(j) = \beta$.

Flow(nF), Fupp(nF) contain the lower and upper bounds l_F and u_F on F(x).

To specify a non-existent lower bound $[l_F]_j = -\infty$, set $Flow(j) \le -infBnd$. For a non-existent upper bound $[u_F]_j = \infty$, set $Fupp(j) \ge infBnd$.

To make the *i*th constraint an equality constraint (say $F_i = \beta$, where $|\beta| < \text{infBnd}$), set $Flow(i) = Fupp(i) = \beta$.

- xnames (nxname), Fnames (nFname) sometimes contain 8-character names for the variables and problem functions. If nxname = 1 or nFname = 1, then names are not used. The printed solution will use generic names for the columns and rows. If nxname = n and nFname = nF, the elements xnames(j) and Fnames(i) should contain the 8-character names of the jth variable and jth row of j.
- xstate(n) sometimes contains a set of initial states for each variable x. See the following discussion of x.
- x(n) contains a set of initial values for x.
 - 1. If Start = 0 or 1 and a BASIS file of some sort is to be input (an OLD BASIS, INSERT, or LOAD file), then xstate and x need not be set.
 - 2. Otherwise, xstate and x must be defined for a Cold start. If nothing special is known about the problem, or if there is no wish to provide special information, you may set xstate(j) = 0, x(j) = 0.0 for all j = 1:n. All variables will be eligible for the initial basis.
 - Less trivially, to say that the optimal value of variable j will probably be equal to one of its bounds, set $\mathtt{xstate}(j) = 4$ and $\mathtt{x}(j) = \mathtt{xlow}(j)$ or $\mathtt{xstate}(j) = 5$ and $\mathtt{x}(j) = \mathtt{xupp}(j)$ as appropriate.
 - 3. For Cold starts with no basis file, a CRASH procedure is used to select an initial basis. The initial basis matrix will be triangular (ignoring certain small entries in each column). The values $\mathtt{xstate}(j) = 0, 1, 2, 3, 4, 5$ have the following meaning:

xstate(j)	State of variable j during CRASH
{0,1,3}	Eligible for the basis. 3 is given preference
$\{2,4,5\}$	Ignored

After CRASH, columns for which $\mathtt{xstate}(j) = 2$ are made superbasic. Other variables not selected for the basis are made nonbasic at the value $\mathtt{x}(j)$ if $\mathtt{xlow}(j) \leq \mathtt{x}(j) \leq \mathtt{xupp}(j)$, or at the value $\mathtt{xlow}(j)$ or $\mathtt{xupp}(j)$ closest to $\mathtt{x}(j)$. See the description of \mathtt{xstate} below (on exit).

- 4. For Warm starts, $\mathtt{xstate}(1:n)$ must be 0, 1, 2 or 3 (probably from some previous call).
- F(nF) sometimes contains a set of initial values for the problem functions F. See the following discussion of Fstate.

Fstate(nF) sometimes contains a set of initial states for the problem functions F.

- 1. If Start = 0 (cold start) or Start = 1 (basis file), and a BASIS file of some sort is to be input (an OLD BASIS file, INSERT file or LOAD file), then Fstate and F need not be set.
- 2. Otherwise, Fstate and F must be defined for a Cold start. If nothing special is known about the problem, or if there is no wish to provide special information, you may set Fstate(i) = 0, F(i) = 0.0 for all i = 1:nF. All rows will be eligible for the initial basis.

Less trivially, to say that the optimal value of row i will probably be equal to one of its bounds, set $\mathtt{Fstate}(i) = 4$ and $\mathtt{F}(i) = \mathtt{Flow}(i)$ or $\mathtt{Fstate}(i) = 5$ and $\mathtt{F}(i) = \mathtt{Fupp}(i)$ as appropriate.

3. For Cold starts with no basis file, a CRASH procedure is used to select an initial basis. The initial basis matrix will be triangular (ignoring certain small entries in each column). The values $\mathtt{xstate}(i) = 0, 1, 2, 3, 4, 5$ have the following meaning:

$ extstyle{ extstyle{Fstate}(i) }$	State of row i during CRASH	
$\{0, 1, 3\}$	Eligible for the basis. 3 is given preference	
$\{2, 4, 5\}$	Ignored	

After CRASH, rows for which $\mathtt{Fstate}(i) = 2$ are made superbasic. Other entries not selected for the basis are made nonbasic at the value $\mathtt{F}(i)$ if $\mathtt{Flow}(i) \leq \mathtt{F}(i) \leq \mathtt{Fupp}(i)$, or at the value $\mathtt{Flow}(i)$ or $\mathtt{Fupp}(i)$ closest to $\mathtt{F}(i)$. See the description of \mathtt{Fstate} below (on exit).

- 4. For Warm starts, Fstate(1:nF) must be 0, 1, 2 or 3 (probably from some previous call).
- Fmul(nF) contains an estimate of λ , the vector of Lagrange multipliers (shadow prices) for the constraints $l_F \leq F(x) \leq u_F$. All nF components must be defined. If nothing is known about λ , set Fmul(i) = 0.0, i = 1:nF.
- nS need not be specified for Cold starts, but should retain its value from a previous call when a Warm start is used.
- cu(lencu), iu(leniu), ru(lenru) are 8-character, integer and real arrays of user workspace. They may be used to pass data or workspace to your function routine usrfun (which has the same parameters). They are not touched by snOptA.

If the function routines don't reference these parameters, you may use any arrays of the appropriate type, such as cw, iw, rw (see next paragraph). Alternatively, you should use the cw, iw, rw arrays if usrfun needs to access snOptA's workspace.

cw(lencw), iw(leniw), rw(lenrw) are 8-character, integer and real arrays of workspace
for snOptA.

lencw, leniw, lenrw must all be at least 500. If variable and function names are specified in xnames and Fnames, then lencw must be at least 500 + n + nF; otherwise lencw = 500 is appropriate. Arguments leniw and lenrw should be as large as possible because it is uncertain how much storage will be needed for the basis factorization. As an estimate, leniw should be about 100(m+n) or larger, and lenrw should be about 200(m+n) or larger.

Appropriate values may be obtained from a call to the routine snMemA (see Section 3.8), or from a preliminary run of snOptA with lencw = leniw = lenrw = 500. If Print level is positive, the required amounts of workspace are printed before snOptA terminates with INFO = 82, 83 or 84. The values are returned in mincw, miniw and minrw.

On exit:

xstate(n) gives the final state of the variables. The elements of xstate have the following meaning:

$\mathtt{xstate}(j)$	State of variable j	Usual value of $\mathbf{x}(j)$
0	nonbasic	$\mathtt{xlow}(j)$
1	nonbasic	$\mathtt{xupp}(j)$
2	superbasic	Between $xlow(j)$ and $xupp(j)$
3	basic	Between $xlow(j)$ and $xupp(j)$

Basic and superbasic variables may be outside their bounds by as much as the Minor feasibility tolerance. Note that if scaling is specified, the feasibility tolerance applies to the variables of the *scaled* problem. In this case, the variables of the original problem may be as much as 0.1 outside their bounds, but this is unlikely unless the problem is very badly scaled. Check the "Primal infeasibility" printed after the EXIT message.

Very occasionally some nonbasic variables may be outside their bounds by as much as the Minor feasibility tolerance, and there may be some nonbasics for which $\mathbf{x}(j)$ lies strictly between its bounds.

If nInf > 0, some basic and superbasic variables may be outside their bounds by an arbitrary amount (bounded by sInf if scaling was not used).

x(n) contains the final values of the variables x.

xmul(ne) is the vector of dual variables for the simple bound constraints $l_x \leq x \leq u_x$.

F(nF) is the final value of the vector F of problem functions.

Fmul(nF) is the vector of dual variables (Lagrange multipliers) for the general constraints $l_F \leq F(x) \leq u_F$.

INFO reports the result of the call to snOptA. Here is a summary of possible values. Further details are in Section 8.6.

Finished successfully

- 1 optimality conditions satisfied
- 2 feasible point found
- 3 requested accuracy could not be achieved

The problem appears to be infeasible

- 11 infeasible linear constraints
- 12 infeasible linear equalities
- 13 nonlinear infeasibilities minimized
- 14 infeasibilities minimized

The problem appears to be unbounded

- 21 unbounded objective
- 22 constraint violation limit reached

Resource limit error

- 31 iteration limit reached
- 32 major iteration limit reached
- 33 the superbasics limit is too small

Terminated after numerical difficulties

- 41 current point cannot be improved
- 42 singular basis
- 43 cannot satisfy the general constraints
- 44 ill-conditioned null-space basis

Error in the user-supplied functions

- 51 incorrect objective derivatives
- 52 incorrect constraint derivatives

Undefined user-supplied functions

- of undefined function at the first feasible point
- 62 undefined function at the initial point
- 63 unable to proceed into undefined region

$User\ requested\ termination$

- 71 terminated during function evaluation
- 74 terminated from monitor routine

Insufficient storage allocated

- 81 work arrays must have at least 500 elements
- 82 not enough character storage
- 83 not enough integer storage
- 84 not enough real storage

Input arguments out of range

- 91 invalid input argument
- 92 basis file dimensions do not match this problem

System error

- 141 wrong number of basic variables
- 142 error in basis package
- mincw, miniw, minrw say how much character, integer and real storage is needed to solve the problem. If snOptA terminates because of insufficient storage (INFO = 82, 83 or 84), these values may be used to define better values of lencw, leniw or lenrw.

If INFO = 82, the work array cw(lencw) is too small. snOptA may be called again with lencw = mincw.

If INFO = 83 or 84, the work arrays iw(leniw) or rw(lenrw) are too small. snOptA may be called again with leniw or lenrw suitably larger than miniw or minrw. (The bigger the better because it is not certain how much storage the basis factorization needs.)

- nS is the final number of superbasic variables.
- nInf, sInf give the number and the sum of the infeasibilities of constraints that lie outside one of their bounds by more than the Minor feasibility tolerance before the solution is unscaled.

If the linear constraints are infeasible, x minimizes the sum of the infeasibilities of the linear constraints subject to the upper and lower bounds being satisfied. In

this case nInf gives the number of components of $A_L x$ lying outside their upper or lower bounds. The nonlinear constraints are not evaluated.

Otherwise, x minimizes the sum of the infeasibilities of the *nonlinear* constraints subject to the linear constraints and upper and lower bounds being satisfied. In this case nInf gives the number of components of F(x) lying outside their upper or lower bounds by more than the Minor feasibility tolerance. Again this is before the solution is unscaled.

3.5. Subroutine snJac

If you set Derivative option 0 and your function routine usrfun provides *none* of the derivatives, you may call subroutine snJac to determine the input arrays iAfun, jAvar, A, iGfun and jGvar for snOptA. These define the pattern of nonzeros in the Jacobian matrix. A typical sequence of calls is

```
call snInit( iPrint, iSumm, ... )
call snJac ( INFO, iPrint, ... )
call snSet ( 'Derivative option = 0', ... )
call snOptA( Start, nF, n, ... )
```

(The Derivative option could also be set in the SPECS file.)

Subroutine snJac determines the sparsity pattern for the Jacobian and identifies the constant elements automatically. To do so, snJac approximates F'(x) at three random perturbations of the given initial point x. If an element of the approximate Jacobian is the same at all three points, then it is taken to be constant. If it is zero, it is taken to be identically zero. Since the random points are not chosen close together, the heuristic will correctly classify the Jacobian elements in the vast majority of cases.

In general, snJac finds that the Jacobian can be permuted to the form $\begin{pmatrix} G(x) & A_3 \\ A_2 & A_4 \end{pmatrix}$, where A_2 , A_3 , A_4 are constant. Note that G(x) might contain elements that are also constant, but snJac must classify them as nonlinear. (This is because snOptA "removes" linear variables from the calculation of F by setting them to zero before calling usrfun.) A knowledgeable user would be able to move such elements from usrfun's F(x) and enter them as part of iAfun, jAvar, A for snOptA.

```
subroutine snJac
    ( INFO, iPrint, iSumm, nF, n, usrfun,
&
      iAfun, jAvar, lenA, neA, A,
      iGfun, jGvar, lenG, neG,
&
&
      x, xlow, xupp, mincw, miniw, minrw,
&
      cu, lencu, iu, leniu, ru, lenru,
      cw, lencw, iw, leniw, rw, lenrw)
external
&
      usrfun
 integer
      INFO, iPrint, iSumm, nF, n, neA, lenA, neG, lenG, mincw,
      miniw, minrw, lencu, lencw, leniu, leniw, lenru, lenrw,
Хr.
      iAfun(lenA), jAvar(lenA), iGfun(lenG), jGvar(lenG),
      iu(leniu), iw(leniw)
double precision
      A(lenA), x(n), xlow(n), xupp(n), ru(lenru), rw(lenrw)
 character
      cu(lencu)*8, cw(lencw)*8
```

On entry:

Most arguments are identical to those of snOptA.

lenA is the dimension of the coordinate arrays iAfun, jAvar and A that hold the coordinates (i, j, A_{ij}) . (lenA ≥ 1).

lenA should be an *overestimate* of the number of elements in the linear part of the Jacobian. The value $lenA = nF \times n$ is an upper bound on the length of A.

lenG is the dimension of the coordinate arrays iffun and jGvar that define the nonlinear Jacobian elements (i, j, G_{ij}) . (lenG ≥ 1).

lenG should be an overestimate of the number of elements in the nonlinear part of the Jacobian. The value $lenG = nF \times n$ is an upper bound on the length of iGfun and jGvar.

On exit:

iAfun(lenA), jAvar(lenA), A(lenA) define the coordinates (i, j) of the nonzero elements of the linear part A of the function F(x) = f(x) + Ax.

The neA triples (iAfun(k), jAvar(k), A(k)), define the row and column indices i = iAfun(k) and j = jAvar(k) of the element $A_{ij} = A(k)$.

neA is the number of nonzeros in A such that F(x) = f(x) + Ax. (neA ≥ 0).

iGfun(lenG), jGvar(lenG) define the coordinates (i,j) of the nonzero elements of the nonlinear part G of the derivatives F'(x) = f'(x) + A = G(x) + A of the function F(x) = f(x) + Ax. The actual elements of G are assigned in the subroutine usrfun.

neG is the number of nonzero entries in G. (neG ≥ 0).

INFO reports the result of the call to snJac.

- 102 Satisfactory coordinates were found.
- 61 User indicates that the functions are undefined at the initial point.
- 71 User requested termination by returning mode < -1 from usrfun.
- 82 Not enough 8-character workspace to solve the problem.
- 83 Not enough integer workspace to solve the problem.
- Not enough real workspace to solve the problem.

mincw, minim, minim say how much character, integer and real storage is needed to build the arrays (i, j, A_{ij}) and (i, j, G_{ij}) . If snJac terminates because of insufficient storage (INFO = 82, 83 or 84), these values may be used to define better values of lencw, leniw or lenrw.

If INFO = 82, the work array cw(lencw) was too small. snJac may be called again with lencw = mincw.

If INFO = 83 or 84, the work arrays iw(leniw) or rw(lenrw) are too small. snJac may be called again with leniw or lenrw suitably larger than miniw or minrw.

3.6. Subroutine usrfun

Your own version of subroutine usrfun is where you define the nonlinear portion f(x) of the problem functions F(x) = f(x) + Ax, along with its gradient elements $G_{ij}(x) = \partial f_i(x)/\partial x_j$. This subroutine is passed to snOptA as the external parameter usrfun. (A dummy subroutine is needed even if $f(x) \equiv 0$ and all functions are linear.)

In general, usrfun should return all function and gradient values on every entry except perhaps the last. This provides maximum reliability and corresponds to the default setting, Derivative option 1.

The elements of G(x) are stored in the array G(1:lenG) in the order specified by snOptA's input arrays iGFun and jGvar (see Section 3.7).

In practice it is often convenient not to code gradients. snOptA is able to estimate them by finite differences, using a call to usrfun for each variable x_j for which some $\partial f_i(x)/\partial x_j$ needs to be estimated. However, this reduces the reliability of the optimization algorithm, and it can be very expensive if there are many such variables x_j .

As a compromise, snOptA allows you to code as many gradients as you like. This option is implemented as follows. Just before the function routine is called, each element of the derivative array G is initialized to a specific value. On exit, any element retaining that value must be estimated by finite differences.

Some rules of thumb follow.

- 1. For maximum reliability, compute all gradients.
- 2. If the gradients are expensive to compute, specify Nonderivative linesearch and use the value of the input parameter needG to avoid computing them on certain entries. (There is no need to compute gradients if needG = 0 on entry to usrfun.)
- 3. If not all gradients are known, you must specify Derivative option 0. You should still compute as many gradients as you can. (It often happens that some of them are constant or even zero.)
- 4. Again, if the known gradients are expensive, don't compute them if needG = 0 on entry to usrfun.
- 5. Use the input parameter Status to test for special actions on the first or last entries.
- 6. While usrfun is being developed, use the Verify option to check the computation of gradients that are supposedly known.
- 7. usrfun is not called until the linear constraints and bounds on x are satisfied. This helps confine x to regions where the functions $f_i(x)$ are likely to be defined. However, be aware of the Minor feasibility tolerance if the functions have singularities on the constraint boundaries.
- 8. Set Status = -1 if some of the functions are undefined. The line search will shorten the step and try again.
- 9. Set Status < -1 if you want snOptA to stop.

```
subroutine usrfun
& ( Status, n, x,
& needf, nF, f,
& needG, lenG, G,
& cu, lencu, iu, leniu, ru, lenru )

integer
& lencu, lenG, leniu, lenru, n, needf, needG, nF, Status,
& iu(leniu)
double precision
& f(nF), G(lenG), ru(lenru), x(n)
character
& cu(lencu)*8
```

On entry:

Status indicates the first and last calls to usrfun.

If Status = 0, there is nothing special about the current call to usrfun.

If Status = 1, snOptA is calling your subroutine for the *first* time. Some data may need to be input or computed and saved.

If $\mathtt{Status} \geq 2$, \mathtt{snOptA} is calling your subroutine for the *last* time. You may wish to perform some additional computation on the final solution.

In general, the last call is made with Status = 2 + INFO/10, where INFO is the integer returned by snOptA (see p. 17). In particular,

```
if \mathtt{Status} = 2, the current x is optimal; if \mathtt{Status} = 3, the problem appears to be infeasible; if \mathtt{Status} = 4, the problem appears to be unbounded; if \mathtt{Status} = 5, an iterations limit was reached.
```

If the functions are expensive to evaluate, it may be desirable to do nothing on the last call. The first executable statement could be if (Status .ge. 2) return.

- n is n, the number of variables, as defined in the call to snOptA.
- $\mathbf{x}(\mathbf{n})$ contains the variables x at which the problem functions are to be calculated. The array \mathbf{x} must not be altered.

```
needf, nF, f(nF) concern the calculation of f(x).

nF is the length of the full vector F(x) = f(x) + Ax as defined in the call to snOptA.

needf indicates if f must be assigned during this call of usrfun:
```

- If needf = 0, f is not required and is ignored.
- If needf > 0, the components of f(x) corresponding to the nonlinear part of F(x) must be calculated and assigned to f.

If $F_i(x)$ is linear and completely defined by A'_i , then the associated value of $f_i(x)$ is ignored and need not be assigned. However, if $F_i(x)$ has a nonlinear portion f_i that happens to be zero at x, then it is still necessary to set $f_i(x) = 0$. If the linear part A'_i of a nonlinear $F_i(x)$ is provided using the snOptA arrays (iAFun, jAvar, A), then it must not be computed as part of $f_i(x)$.

To simplify the code, you may ignore the value of needf and compute f(x) on every entry to usrfun.

needf may also be ignored with Derivative linesearch and Derivative option 1 (both defaults). In this case, needf is always 1, and f must always be assigned.

- needG, lenG, G(lenG) concern the calculation of the derivatives of the function f(x).

 lenG is the length of the coordinate arrays iGvar and jGfun in the call to snOptA.

 needG indicates if G must be assigned during this call of usrfun:
 - If needG = 0, G is not required and is ignored.
 - If needG > 0, the partial derivatives of f(x) must be calculated and assigned to G. For each k = 1:lenG, the value of G(k) should be $\partial f_i(x)/\partial x_j$, where i = iGfun(k), j = jGvar(k).
- cu(lencu), iu(leniu), ru(lenru) are the character, integer and real arrays of user workspace provided to snOptA. They may be used to pass information into the function routines and to preserve data between calls.

In special applications the functions may depend on some of the internal variables stored in snOptA's workspace arrays cw, iw, rw. For example, the 8-character problem name Prob is stored in cw(51), and the dual variables are stored in rw(1FMul) onward, where 1FMul = iw(329). These will be accessible to usrfun if snOptA is called with parameters cu, iu, ru the same as cw, iw, rw.

If you still require workspace, elements rw(501:maxru) and rw(maxrw+1:lenru) are set aside for this purpose, where maxru = iw(2). Similarly for workspace in cw and rw. (See the Total and User workspace options.)

On exit:

Status may be used to indicate that you are unable to evaluate f or its gradients at the current x. (For example, the problem functions may not be defined there).

During the line search, f(x) is evaluated at points $x = x_k + \alpha p_k$ for various steplengths α , where $f(x_k)$ has already been evaluated satisfactorily. For any such x, if you set Status = -1, snOptA will reduce α and evaluate f again (closer to x_k , where it is more likely to be defined).

If for some reason you wish to terminate the current problem, set Status ≤ -2 .

- f(nF) contains the computed functions f(x) (except perhaps if needf = 0).
- G(neG) contains the computed derivatives G(x) (except perhaps if needG = 0).

These derivative elements must be stored in G in exactly the same positions as implied by the definitions of snOptA's arrays iGfun, jGvar. There is no internal check for consistency (except indirectly via the Verify option), so great care is essential.

3.7. Example usrfun

Here we give subroutine usrfun for the problem

minimize
$$3x_1 + 5x_2 + (x_1 + x_3 + x_4)^2$$

subject to $x_1 + x_3^2 + x_4^2 = 2$
 $2x_3 + 4x_4 \ge 0$
 $x_2 + x_4^4 = 4$

plus bounds on x. This problem has 4 variables, a nonlinear objective function, 2 nonlinear constraints, and 1 linear constraint. The vector of functions is

$$F(x) = \begin{pmatrix} 3x_1 + 5x_2 + (x_1 + x_3 + x_4)^2 \\ x_1 + x_3^2 + x_4^2 \\ 2x_3 + 4x_4 \\ x_2 + x_4^4 \end{pmatrix}.$$

The Jacobian of F is the matrix

$$F'(x) = \begin{pmatrix} 3 + 2(x_1 + x_3 + x_4) & 5 & 2(x_1 + x_3 + x_4) & 2(x_1 + x_3 + x_4) \\ 1 & 0 & 2x_3 & 2x_4 \\ 0 & 0 & 2 & 4 \\ 0 & 1 & 4x_4^3 \end{pmatrix}.$$

We can write F(x) = f(x) + Ax and F'(x) = f'(x) + A = G(x) + A, where

$$f(x) = \begin{pmatrix} 3x_1 + (x_1 + x_3 + x_4)^2 \\ x_3^2 + x_4^2 \\ 0 \\ x_4^4 \end{pmatrix}, \qquad A = \begin{pmatrix} 0 & 5 & 0 & 0 \\ 1 & 0 & 0 & 0 \\ 0 & 0 & 2 & 4 \\ 0 & 1 & 0 & 0 \end{pmatrix}$$

and G is the non-overlapping matrix

$$G(x) = \begin{pmatrix} 3 + 2(x_1 + x_3 + x_4) & 0 & 2(x_1 + x_3 + x_4) & 2(x_1 + x_3 + x_4) \\ 0 & 0 & 2x_3 & 2x_4 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 4x_4^3 \end{pmatrix}.$$

The calling program must assign many parameters for input to snOptA, including

$$nF = 4$$
, $n = 4$, $ObjRow = 1$, $neA = 5$, $neG = 6$ $lenG = 6$ $(\ge neG)$.

Some of these parameters are passed to subroutine usrfun (next page). Note that usrfun works only with the nonlinear variables (x_1, x_3, x_4) that appear in f and G. The array f is set to f(x), excluding the term Ax (which is evaluated separately by snOptA). The array G is set to all nonzero entries of G(x), excluding the matrix A.

For illustration, we test needF and needG to economize on function and gradient evaluations (even though they are cheap here). Note that Nonderivative linesearch would have to be specified, otherwise all entries would have needG = 1. We also test State to print a message on the first and last entries.

```

3.8. Subroutine snMemA

This routine estimates the size of the workspace arrays cw, iw, rw required to solve an optimization problem of given dimensions. snMemA is not strictly needed in f77 because all workspace must be defined explicitly in the driver program at compile time. It is available for users wishing to allocate storage dynamically in f90 or C.

The actual storage required also depends on the values of the following options:

```
Hessian full or Hessian limited memory and Hessian updates Reduced Hessian dimension Superbasics limit
```

If these options have not been set, default values are assumed. Ideally the correct values should be set *before* the call to snMemA.

```
subroutine snMemA
& ( INFO, nF, n, nxname, nFname, neA, neG,
& mincw, miniw, minrw,
& cw, lencw, iw, leniw, rw, lenrw )

integer
& INFO, lencw, leniw, lenrw, mincw, miniw, minrw, n, neA, neG,
& nF, nFname, nxname, iw(leniw)
double precision
& rw(lenrw)
character
& cw(lencw)*8
```

The arguments nF, n, nxname, nFname, neA, neG define the problem being solved and are identical to the arguments used in the call to snOptA (see Section 3.4). For a sequence of problems, snMemA may be called once with overestimates of these quantities.

On entry:

lencw, leniw, lenrw must be of length at least 500.

cw(lencw), iw(leniw), rw(lenrw) are 8-character, integer and real arrays of workspace
for snMemA.

On exit:

INFO reports the result of the call to snMemA. Here is a summary of possible values. Further details are in Section 8.6.

Insufficient storage allocated

81 work arrays must have at least 500 elements

Finished successfully

104 memory requirements estimated

mincw, miniw, minrw estimate how much character, integer and real storage is needed to solve the problem.

To use snMemA, the first step is to allocate the work arrays. These may be temporary arrays tmpcw, tmpiw, tmprw (say) or the snOptA arrays cw, iw, rw, which will be reallocated after the storage limits are known. Here we illustrate the use of snMemA using the same arrays for snMemA and snOptA. Note that the snMemA arrays are used to store the optional parameters, and so any temporary arrays must be copied into the final cw, iw, rw arrays in order to retain the options.

The work arrays must have length at least 500, so we define

```
ltmpcw = 500
ltmpiw = 500
ltmprw = 500
```

As with all SNOPT routines, snInit must be called to initialize the optional parameters to their default values:

```
call snInit
& ( iPrint, iSumm, cw, ltmpcw, iw, ltmpiw, rw, ltmprw )
```

This installs ltmpcw, ltmprw as the default internal upper limits on the snOptA workspace (see the description of Total real workspace in Section 7.6). They are used to compute the boundaries of any user-defined workspace in cw, iw, or rw.

The next step is to call snMemA to obtain mincw, miniw, minrw as estimates of the storage needed by snOptA:

```
call snMemA
& ( INFO, nF, n, nxname, nFname, neA, neG,
& mincw, miniw, minrw,
& cw, ltmpcw, iw, ltmpiw, rw, ltmprw )
```

The output values of mincw, miniw, minrw may now be used to define the lengths of the snOptA work arrays:

```
lencw = mincw
leniw = miniw
lenrw = minrw
```

These values may be used in f90 or C to allocate the final work arrays for the problem.

One last step is needed before snOptA is called. The current upper limits ltmpcw, ltmpiw, ltmprw must be replaced by the estimates mincw, miniw, minrw. This can be done using the option setting routine snSeti as follows:

```
Errors = 0
                           ! Counts the number of errors
 iPrt
                           ! Suppress print
                                              output
                           ! Suppress summary output
 iSum
       = 0
 call snSeti
   ( 'Total character workspace', lencw, iPrt, iSum, Errors,
      cw, ltmpcw, iw, ltmpiw, rw, ltmprw )
 call snSeti
   ( 'Total integer
                       workspace', leniw, iPrt, iSum, Errors,
     cw, ltmpcw, iw, ltmpiw, rw, ltmprw)
call snSeti
                       workspace', lenrw, iPrt, iSum, Errors,
&
  ( 'Total real
     cw, ltmpcw, iw, ltmpiw, rw, ltmprw)
```

An alternative way is to call snInit again with arguments lencw, leniw, lenrw:

```
call snInit & ( iPrint, iSumm, cw, lencw, iw, leniw, rw, lenrw )
```

However, this has the twin effects of resetting all options to their default values and reprinting the SNOPT banner (unless iPrint = 0 and iSumm = 0 are set for the PRINT and SUMMARY files).

4. The snOptB interface

snOptB is the "basic" user interface with arguments identical to versions of SNOPT up to version 5.3-4. The optimization problem is assumed to be in the form of SparseNP (p. 3) with the data ordered so that nonlinear constraints and variables come first. A typical invocation of snOptB is

```
call snInit( iPrint, iSumm, ... )
call snSpec( ... )
call snOptB( Start, m, n, ne, ... )
```

Subroutine snOpt is identical to snOptB, and the analogous call provides compatibility with previous versions of SNOPT:

```
call snOpt (Start, m, n, ne, ...)
```

4.1. Subroutines used by snOptB

snOptB is accessed via the following routines:

```
snInit (Section 1.6) must be called before any other snOptB routines.

snSpec (Section 7.3) may be called to input a SPECS file (a list of run-time options).

snSet, snSeti, snSetr (Section 7.4) may be called to specify a single option.

snGet, snGetc, snGeti, snGetr (Section 7.5) may be called to obtain an option's current value.

funcon, funobj (Section 4.5) are supplied by the user and called by snOptB. They define the constraint functions f(x) and objective function f_0(x).

snOptB, snOpt (Section 4.4) are the main solvers. They are identical.

snMemB (Section 4.10) computes the size of the workspace arrays cw, iw, rw required for given problem dimensions. Intended for Fortran 90 and C drivers that reallocate workspace if necessary.
```

The user routines funcon and funobj have a fixed parameter list but may have any convenient name. They are passed to snOptB and snOpt as parameters.

4.2. Identifying structure in the objective and constraints

Consider the following nonlinear optimization problem with four variables x = (u, v, w, z):

minimize
$$(u+v+w)^2 + 3w + 5z$$
subject to
$$u^2 + v^2 + w = 2$$

$$v^4 + z = 4$$

$$2u + 4v > 0$$

with bounds $w \ge 0$, $z \ge 0$. This problem has several characteristics that can be exploited:

- The objective function is the sum of a *nonlinear* function of the three variables x' = (u, v, w) and a *linear* function of (potentially) all variables x.
- The first two constraints are nonlinear, and the third constraint is linear.

• Each nonlinear constraint involves the sum of a *nonlinear* function of the two variables x'' = (u, v) and a *linear* function of the remaining variables y'' = (w, z).

The nonlinear terms are defined by user-written subroutines funobj and funcon, which involve only x' and x'', the appropriate subsets of variables.

For the objective, we define the function $f_0(u, v, w) = (u + v + w)^2$ to include only the nonlinear terms. The variables x' = (u, v, w) are known as nonlinear objective variables, and their dimension is specified by the snOptB input parameter nnObj (= 3 here). The linear part 3w + 5z of the objective is treated as an additional linear constraint whose row index is specified by the input parameter iObj. Thus, the full objective has the form $f_0(x') + d^T x$, where x' is the first nnObj variables, $f_0(x')$ is defined by subroutine funobj, and d is a constant vector that forms row iObj of the full Jacobian matrix. Choosing iObj = 4, we think of the problem as

minimize
$$(u+v+w)^2 + s_4$$
subject to
$$u^2 + v^2 + w = 2$$

$$v^4 + z = 4$$

$$2u + 4v \geq 0$$

$$3w + 5z = s_4$$

with bounds $w \geq 0$, $z \geq 0$, $-\infty \leq s_4 \leq \infty$, where s_4 is treated *implicitly* as the 4th slack variable.

Similarly for the constraints, we define a vector function f(u,v) to include just the nonlinear terms. In this example, $f_1(u,v) = u^2 + v^2$ and $f_2(u,v) = u^4 + v^4$. The number of nonlinear constraints (the dimension of f) is specified by the input parameter nnCon = 2. The variables x'' = (u,v) are known as nonlinear Jacobian variables, with dimension specified by nnJac = 2. Thus, the constraint functions and the linear part of the objective have the form

$$\begin{pmatrix} f(x'') + A_3 y'' \\ A_2 x'' + A_4 y'' \end{pmatrix}, \tag{4.1}$$

where x'' is the first nnJac variables, f(x'') is defined by subroutine funcon, and y'' contains the remaining variables. The full Jacobian is of the form

$$A = \begin{pmatrix} f'(x'') & A_3 \\ A_2 & A_4 \end{pmatrix}, \tag{4.2}$$

with the Jacobian of f always appearing in the *top left corner* of A. The sparsity pattern of f'(x'') and the constant matrices A_2 , A_3 , A_4 are input column-wise via the array parameters Acol, indA, locA. (Elements that are identically zero need not be included.)

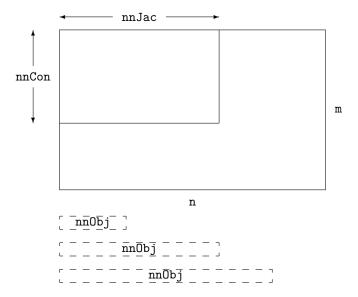

The inequalities $l_1 \leq f(x'') + A_3 y'' \leq u_1$ and $l_2 \leq A_2 x + A_4 y'' \leq u_2$ implied by the constraint functions (4.1) are known as the *nonlinear* and *linear* constraints respectively. Together, these two sets of inequalities constitute the *qeneral constraints*.

In general, the vectors x' and x'' have different dimensions, but they always overlap, in the sense that the shorter vector is always the beginning of the other. In the example, the nonlinear Jacobian variables (u,v) are an ordered subset of the nonlinear objective variables (u,v,w). In other cases it could be the other way round—whichever is the most convenient—but the first way keeps J(x'') smaller.

Together the nonlinear objective and nonlinear Jacobian variables comprise the *nonlinear* variables. The number of nonlinear variables is therefore the *larger* of the dimensions of x' and x''.

4.3. Problem dimensions

The following picture illustrates the problem structure just described:

The dimensions are all input parameters to subroutine \mathtt{snOptB} (see the next section). For linear programs, \mathtt{nnCon} , \mathtt{nnJac} and \mathtt{nnObj} are all zero. If a linear objective term exists, \mathtt{iObj} points to one of the bottom rows $(\mathtt{nnCon} < \mathtt{iObj} \leq \mathtt{m})$.

The dashed boxes indicate that a nonlinear objective function $f_0(x')$ may involve either a subset or a superset of the variables in the nonlinear constraint functions f(x''), counting from the left. Thus, nn0bj \leq nnJac or vice versa.

Sometimes the objective and constraints really involve disjoint sets of nonlinear variables. We then recommend ordering the variables so that $\mathtt{nn0bj} > \mathtt{nnJac}$ and x' = (x'', x'''), where the objective is nonlinear in just the last vector x'''. Subroutine \mathtt{funobj} should set $\mathtt{g}(j) = 0.0$ for $j = 1:\mathtt{nnJac}$. It should then set as many remaining gradients as possible—preferably all!

4.4. Subroutine snOptB

Problem SparseNP is solved by a call to subroutine snOptB, whose parameters are defined here. Note that most machines use double precision declarations as shown, but some machines use real. The same applies to the user routines funcon and funobj.

```
subroutine snOptB
    (Start, m, n, neA, nName,

 character*(*)
      Start
 character
      Prob*8, cu(lencu)*8, cw(lencw)*8, Names(nName)*8
```

On entry:

m

start is a character string that specifies how a starting basis (and certain other items) are to be obtained.

'Cold' requests that the CRASH procedure be used to choose an initial basis, unless a basis file is provided via OLD BASIS, INSERT or LOAD in the SPECS file.

'Basis file' is the same as start = 'Cold' but is more meaningful when a basis file is given.

'Warm' means that a basis is already defined in hs (probably from an earlier call).

is m, the number of general constraints. This is the number of rows in the full constraint matrix A in (4.2). (m > 0)

Note that A must have at least one row. If your problem has no constraints, or only upper and lower bounds on the variables, then you must include a dummy row with sufficiently wide upper and lower bounds. See the discussion of the parameters Acol, indA, locA below.

- n is n, the number of variables, excluding slacks. This is the number of columns in A. (n > 0)
- neA is the number of nonzero entries in A (including the Jacobian for any nonlinear constraints). (neA > 0)
- nName is the number of column and row names provided in the character array Names. If nName = 1, there are no names. Generic names will be used in the printed solution. Otherwise, nName = n + m and all names must be provided.
- nnCon is m_1 , the number of nonlinear constraints. (nnCon ≥ 0)
- nn0bj is n'_1 , the number of nonlinear objective variables. (nn0bj ≥ 0)
- nnJac is n_1'' , the number of nonlinear Jacobian variables. If nnCon = 0, nnJac = 0. If nnCon > 0, nnJac > 0.
- iObj says which row of A is a free row containing a linear objective vector c. If there is no such vector, iObj = 0. Otherwise, this row must come after any nonlinear rows, so that nnCon < iObj < m.
- ObjAdd is a constant that will be added to the objective for printing purposes. Typically ObjAdd = 0.0d+0.
- Prob is an 8-character name for the problem. Prob is used in the printed solution and in some routines that output BASIS files. A blank name may be used.
- funcon is the name of a subroutine that calculates the vector of nonlinear constraint functions f(x) and (optionally) its Jacobian for a specified vector x (the first nnJac elements of $\mathbf{x}(*)$). funcon must be declared external in the routine that calls \mathtt{snOptB} . For a detailed description of funcon, see Section 4.6.
- funobj is the name of a subroutine that calculates the objective function $f_0(x)$ and (optionally) its gradient for a specified vector x (the first nnObj elements of $\mathbf{x}(*)$). funobj must be declared external in the routine that calls snOptB. For a detailed description of funobj, see Section 4.7.
- Acol(neA), indA(neA), locA(n+1) define the nonzero elements of the constraint matrix A (4.2), including the Jacobian matrix associated with nonlinear constraints. The nonzeros are stored column-wise. A pair of values (Acol(k), indA(k)) contains a matrix element and its corresponding row index, and the array locA(*) is a set of pointers to the beginning of each column of A within Acol(*) and indA(*). Thus for j = 1:n, the entries of column j are held in Acol(k:l) and their corresponding row indices are in indA(k:l), where k = locA(j) and l = locA(j+1) 1,

Note: Every element of Acol(*) must be assigned a value in the calling program.

In general, elements in the nonlinear part of Acol(*) (see the notes below) may be any dummy value (e.g., zero) because they are initialized at the first point that is feasible with respect to the linear constraints.

If Derivative level = 2 or 3, the nonlinear part of Acol(*) may be used to define any constant Jacobian elements. If funcon does not define all entries of gCon(*), the missing values will be obtained from Acol(*).

- 1. It is essential that locA(1) = 1 and locA(n+1) = neA + 1.
- 2. The Jacobian f'(x) forms the top left corner of Acol and indA (see Section 4.2). If a Jacobian column j $(1 \le j \le \mathtt{nnJac})$ contains any entries $\mathtt{Acol}(k)$, $\mathtt{indA}(k)$ associated with nonlinear constraints $(1 \le \mathtt{indA}(k) \le \mathtt{nnCon})$, those entries must come before any entries belonging to linear constraints.

- 3. The row indices indA(k) for a column may be in any order, subject to Jacobian entries appearing first. Subroutine funcon must define the Jacobian entries gCon(*) in the same order (except gCon does not contain elements in linear constraints).
- 4. If your problem has no constraints, or just bounds on the variables, you may include a dummy "free" row with a single (zero) element by setting Acol(1) = 0.0, indA(1) = 1, locA(1) = 1, and locA(j) = 2 for j = 2:n+1. This row is made "free" by setting its bounds to be bl(n+1) = -infBnd and bu(n+1) = infBnd, where infBnd is typically 1.0e+20 (see the next paragraph).
- $\mathtt{bl}(\mathtt{n+m})$, $\mathtt{bu}(\mathtt{n+m})$ contains the lower and upper bounds l and u on the variables and slacks (x,s). The first n entries of \mathtt{bl} , \mathtt{bu} , \mathtt{hs} and \mathtt{x} refer to the variables x. The last m entries refer to the slacks s.

To specify a non-existent lower bound $l_j = -\infty$, set $bl(j) \leq -\inf Bnd$, where infBnd is the Infinite Bound, whose default value is 10^{20} . To specify a non-existent upper bound $u_j = \infty$, set $bu(j) \geq \inf Bnd$.

To make the *i*th constraint an equality constraint (say $s_i = \beta$, where $|\beta| < \text{infBnd}$), set $bl(n+i) = bu(n+i) = \beta$. To fix the *j*th variable (say $x_j = \beta$, where $|\beta| < \text{infBnd}$), set $bl(j) = bu(j) = \beta$.

For the data to be meaningful, it is required that $bl(j) \leq bu(j)$ for all j.

- Names (nName) sometimes contains 8-character names for the variables and constraints. If nName = 1, Names is not used. The printed solution will use generic names for the columns and row. If nName = n + m, Names(j) should contain the 8-character name of the jth variable (j = 1: n + m). If j = n + i, the jth variable is the ith row.
- hs(n+m) sometimes contains a set of initial states for each variable x, or for each variable and slack (x, s). See the following discussion of x.
- x(n+m) sometimes contains a set of initial values for x or (x,s).
 - 1. If start = 'Cold' or 'Basis file' and a BASIS file of some sort is to be input (an OLD BASIS, INSERT, or LOAD file), then hs and x need not be set.
 - 2. Otherwise, hs(1:n) and x(1:n) must be defined for a Cold start. If nothing special is known about the problem, or if there is no wish to provide special information, you may set hs(j) = 0, x(j) = 0.0 for all j = 1:n. All variables will be eligible for the initial basis.
 - Less trivially, to say that the optimal value of variable j will probably be equal to one of its bounds, set hs(j) = 4 and x(j) = bl(j) or hs(j) = 5 and x(j) = bu(j) as appropriate.
 - 3. For Cold starts with no basis file, a CRASH procedure is used to select an initial basis. The initial basis matrix will be triangular (ignoring certain small entries in each column). The values $\mathtt{hs}(j) = 0, 1, 2, 3, 4, 5$ have the following meaning:

$\mathtt{hs}(j)$	State of variable j during CRASH
$\{0, 1, 3\}$	Eligible for the basis. 3 is given preference
$\{2, 4, 5\}$	Ignored

After CRASH, columns for which hs(j) = 2 are made superbasic. Other entries not selected for the basis are made nonbasic at the value x(j) if $bl(j) \le x(j) \le x(j)$

 $\mathtt{bu}(j)$, or at the value $\mathtt{bl}(j)$ or $\mathtt{bu}(j)$ closest to $\mathtt{x}(j)$. See the description of hs below (on exit).

- 4. For Warm starts, all of hs(1:n+m) must be 0, 1, 2 or 3 (probably from some previous call) and all of x(1:n+m) must have values.
- pi contains an estimate of λ , the vector of Lagrange multipliers (shadow prices) for the nonlinear constraints. The first nnCon components must be defined. If nothing is known about λ , set pi(i) = 0.0, i = 1:nnCon.
- nS need not be specified for Cold starts, but should retain its value from a previous call when a Warm start is used.
- cu(lencu), iu(leniu), ru(lenru) are 8-character, integer and real arrays of user work-space. They may be used to pass data or workspace to your function routines funcon and funobj (which have the same parameters). They are not touched by snOptB.

If the function routines don't reference these parameters, you may use any arrays of the appropriate type, such as cw, iw, rw (see next paragraph). Alternatively, you should use the latter arrays if funcon and funobj need to access snOptB's workspace.

cw(lencw), iw(leniw), rw(lenrw) are 8-character, integer and real arrays of workspace
for snOptB.

lencw, leniw, lenrw must all be at least 500. In general, lencw = 500 is appropriate but leniw and lenrw should be as large as possible because it is uncertain how much storage will be needed for the basis factorization. As an estimate, leniw should be about 100(m+n) or larger, and lenrw should be about 200(m+n) or larger.

Appropriate values may be obtained from a preliminary run with lencw = leniw = lenrw = 500. If Print level is positive, the required amounts of workspace are printed before snOptB terminates with INFO = 82, 83 or 84. The values are returned in mincw, miniw and minrw.

On exit:

hs(n+m) is the final state vector. The elements of hs have the following meaning:

$\mathtt{hs}(j)$	State of variable j	Usual value of $\mathbf{x}(j)$
0	nonbasic	$\mathtt{bl}(j)$
1	nonbasic	$\mathtt{bu}(j)$
2	superbasic	Between $\mathtt{bl}(j)$ and $\mathtt{bu}(j)$
3	basic	Between $\mathtt{bl}(j)$ and $\mathtt{bu}(j)$

Basic and superbasic variables may be outside their bounds by as much as the Minor feasibility tolerance. Note that if scaling is specified, the feasibility tolerance applies to the variables of the *scaled* problem. In this case, the variables of the original problem may be as much as 0.1 outside their bounds, but this is unlikely unless the problem is very badly scaled. Check the "Primal infeasibility" printed after the EXIT message.

Very occasionally some nonbasic variables may be outside their bounds by as much as the Minor feasibility tolerance, and there may be some nonbasics for which $\mathbf{x}(j)$ lies strictly between its bounds.

If nInf > 0, some basic and superbasic variables may be outside their bounds by an arbitrary amount (bounded by sInf if scaling was not used).

x(n+m) is the final variables and slacks (x,s).

- pi(m) is the vector of dual variables π (a set of Lagrange multipliers for the general constraints).
- rc(n+m) is a vector of reduced costs, $g (A I)^T \pi$, where g is the gradient of the objective if x is feasible (or the gradient of the Phase-1 objective otherwise). The last m entries are π .
- INFO reports the result of the call to snOptB. Here is a summary of possible values. Further details are in Section 8.6.

Finished successfully

- 1 optimality conditions satisfied
- 2 feasible point found
- 3 requested accuracy could not be achieved

The problem appears to be infeasible

- 11 infeasible linear constraints
- 12 infeasible linear equalities
- 13 nonlinear infeasibilities minimized
- 14 infeasibilities minimized

The problem appears to be unbounded

- 21 unbounded objective
- 22 constraint violation limit reached

Resource limit error

- 31 iteration limit reached
- 32 major iteration limit reached
- 33 the superbasics limit is too small

Terminated after numerical difficulties

- 41 current point cannot be improved
- 42 singular basis
- 43 cannot satisfy the general constraints
- 44 ill-conditioned null-space basis

Error in the user-supplied functions

- 51 incorrect objective derivatives
- 52 incorrect constraint derivatives

Undefined user-supplied functions

- 61 undefined function at the first feasible point
- 62 undefined function at the initial point
- 63 unable to proceed into undefined region

User requested termination

- 72 terminated during constraint evaluation
- 73 terminated during objective evaluation
- 74 terminated from monitor routine

Insufficient storage allocated

- 81 work arrays must have at least 500 elements
- 82 not enough character storage
- 83 not enough integer storage
- 84 not enough real storage

Input arguments out of range

- 91 invalid input argument
- 92 basis file dimensions do not match this problem

System error

- 141 wrong number of basic variables
- 142 error in basis package
- mincw, miniw, minrw say how much character, integer and real storage is needed to solve the problem. If snOptB terminates because of insufficient storage (INFO = 82, 83 or 84), these values may be used to define better values of lencw, leniw or lenrw.

If INFO = 82, the work array cw(lencw) was too small. snOptB may be called again with lencw = mincw.

If INFO = 83 or 84, the work arrays iw(leniw) or rw(lenrw) are too small. snOptB may be called again with leniw or lenrw suitably larger than miniw or minrw. (The bigger the better, since it is not certain how much storage the basis factorization needs.)

- nS is the final number of superbasic variables.
- nInf, sInf give the number and the sum of the infeasibilities of constraints that lie outside their bounds by more than the Feasibility tolerance.

If the *linear* constraints are infeasible, x minimizes the sum of the infeasibilities of the linear constraints subject to the upper and lower bounds being satisfied. In this case nInf gives the number of components of A_Lx lying outside their upper or lower bounds. The nonlinear constraints are not evaluated.

Otherwise, x minimizes the sum of the infeasibilities of the *nonlinear* constraints subject to the linear constraints and upper and lower bounds being satisfied. In this case nInf gives the number of components of f(x) lying outside their upper or lower bounds.

Obj is the final value of the nonlinear part of the objective function. If nInf = 0, Obj is the nonlinear objective, if any. If nInf > 0 but the linear constraints are feasible, then Obj is the nonlinear objective. If nInf > 0 and the linear constraints are infeasible, Obj is zero.

Note that Obj does not include contributions from the constant term ObjAdd or the objective row, if there is one. The final value of the objective being optimized is ObjAdd + x(n+iObj) + Obj, where iObj is the index of the objective row in A.

4.5. User-supplied routines required by snOptB

The user must provide subroutines to define the nonlinear parts of the objective function and nonlinear constraints. They are passed to snOptB as external parameters funobj and funcon. (A dummy subroutine must be provided if the objective or constraints are purely linear.)

Be careful when coding the call to snOptB: the parameters are ordered alphabetically as funcon, funobj. The first call to each function routine is also in that order.

In general, these subroutines should return all function and gradient values on every entry except perhaps the last. This provides maximum reliability and corresponds to the default setting, Porivative level = 3.

In practice it is often convenient not to code gradients. snOptB is able to estimate gradients by finite differences, by making a call to funcon or funobj for each variable x_j whose partial derivatives need to be estimated. However, this reduces the reliability of the optimization algorithms, and it can be very expensive if there are many such variables x_j .

As a compromise, snOptB allows you to code as many gradients as you like. This option is implemented as follows. Just before a function routine is called, each element of the gradient array is initialized to a specific value. On exit, any element retaining that value must be estimated by finite differences.

Some rules of thumb follow.

- 1. For maximum reliability, compute all function and gradient values.
- 2. If the gradients are expensive to compute, specify Nonderivative linesearch and use the input parameter mode to avoid computing them on certain entries. (Don't compute gradients if mode = 0.)
- 3. If not all gradients are known, you must specify Derivative level < 3. You should still compute as many gradients as you can. (It often happens that some of them are constant or even zero.)
- 4. Again, if the known gradients are expensive, don't compute them if mode = 0.
- 5. Use the input parameter nState to test for special actions on the first or last entries.
- 6. While the function routines are being developed, use the Verify option to check the computation of gradient elements that are supposedly known. The Start and Stop options may also be helpful.
- 7. The function routines are not called until the linear constraints and bounds on x are satisfied. This helps confine x to regions where the nonlinear functions are likely to be defined. However, be aware of the Minor feasibility tolerance if the functions have singularities,
- 8. Set mode = -1 if the functions are undefined. The linesearch will shorten the step and try again.
- 9. Set mode ≤ -2 if you want snOptB to stop.

4.6. Subroutine funcon

This subroutine must compute the nonlinear constraint functions f(x) and (optionally) their gradients f'(x), where x is the current value of the Jacobian variables x''. The jth column of the Jacobian matrix f'(x) is the vector $\partial f/\partial x_j$.

For small problems (or large dense ones) it is convenient to treat the Jacobian as a dense matrix and declare gCon as a two-dimensional array gCon(*,*) (stored column-wise in Fortran). It is then simple to compute the Jacobian by rows or by columns. For sparse Jacobians, it is essential to use a one-dimensional array gCon(*) to conserve storage.

```
subroutine funcon
         ( mode, nnCon, nnJac, neJac,
     &
           x, fCon, gCon, nState,
           cu, lencu, iu, leniu, ru, lenru)
      integer
           lencu, leniu, lenru, mode, neJac, nnCon, nnJac, nState,
           iu(leniu)
      double precision
           fCon(nnCon), ru(lenru), x(nnJac)
      character
           cu(lencu)*8
*!!
     double precision
                         gCon(nnCon,nnJac)
                                             ! Dense
                                                      ! Choose ONE of these
      double precision
                         gCon(neJac)
                                             ! Sparse
```

On entry:

mode indicates whether fCon or gCon or both must be assigned during the present call of funcon $(0 \le mode \le 2)$.

This parameter can be ignored if Derivative linesearch is selected (the default) and if Derivative level = 2 or 3. In this case, mode will always have the value 2, and all elements of fCon and gCon must be assigned (except perhaps constant elements of gCon).

Otherwise, snOptB will call funcon with mode = 0, 1 or 2. You may test mode to decide what to do:

- If mode = 2, assign fCon and the known components of gCon.
- If mode = 1, assign the known components of gCon. fCon is ignored.
- If mode = 0, only fCon need be assigned; gCon is ignored.

nnCon is the number of nonlinear constraints (nnCon > 0). These must be the first nnCon constraints in the problem.

nnJac is the number of variables involved in f(x) (0 < nnJac $\leq n$). These must be the first nnJac variables in the problem.

neJac is the number of nonzero elements in gCon. If gCon is stored as a two-dimensional array, then $neJac = nnCon \times nnJac$.

x(nnJac) contains the nonlinear Jacobian variables x. The array x must not be altered.

nState indicates the first and last calls to funcon.

If nState = 0, there is nothing special about the current call to funcon.

If nState = 1, snOptB is calling your subroutine for the *first* time. Some data may need to be input or computed and saved. Note that if there is a nonlinear objective, the first call to funcon will occur *before* the first call to funobj.

If $nState \ge 2$, snOptB is calling your subroutine for the *last* time. You may wish to perform some additional computation on the final solution. Note again that the last call to funcon will occur *before* the last call to funobj.

In general, the last call is made with nState = 2 + INFO/10, where INFO is the integer returned by snOptB (see p. 38). In particular,

```
if nState = 2, the current x is optimal; if nState = 3, the problem appears to be infeasible; if nState = 4, the problem appears to be unbounded; if nState = 5, an iterations limit was reached.
```

If the functions are expensive to evaluate, it may be desirable to do nothing on the last call. The first executable statement could be if (Status .ge. 2) return.

cu(lencu), iu(leniu), ru(lenru) are the character, integer and real arrays of user workspace provided to snOptB. They may be used to pass information into the function routines and to preserve data between calls.

In special applications the functions may depend on some of the internal variables stored in snOptB's workspace arrays cw, iw, rw. For example, the 8-character problem name Prob is stored in cw(51), and the dual variables are stored in rw(1xMul) onward, where 1xMul = iw(316). These will be accessible to both funcon and funobj if snOptB is called with parameters cu, iu, ru the *same* as cw, iw, rw.

If you still require user workspace, elements rw(501:maxru) and rw(maxrw+1:lenru) are set aside for this purpose, where maxru = iw(2). Similarly for workspace in cw and rw. (See the Total and User workspace options.)

On exit:

fCon(nnCon) contains the computed constraint vector f(x) (except perhaps if mode = 1).

gCon(nnCon,nnJac) or gCon(neJac) contains the computed Jacobian f'(x) (except perhaps if mode = 0). These gradient elements must be stored in gCon consistently with the arrays Acol, indA, locA that define the sparsity pattern of f(x'') and A_2 in (4.2), excluding the elements of A_2 . There is no internal check for consistency (except indirectly via the Verify option), so great care is essential.

mode may be used to indicate that you are unable to evaluate f or its gradients at the current x. (For example, the problem functions may not be defined there).

During the line search, f(x) is evaluated at points $x = x_k + \alpha p_k$ for various steplengths α , where $f(x_k)$ has already been evaluated satisfactorily. For any such x, if you set mode = -1, snOptB will reduce α and evaluate f again (closer to x_k , where it is more likely to be defined).

If for some reason you wish to terminate the current problem, set $mode \leq -2$.

4.7. Subroutine funobj

This subroutine must calculate the nonlinear objective function $f_0(x)$ and (optionally) its gradient $g(x) = \partial f_0(x)/\partial x$, where x is the current value of the objective variables x'.

```
subroutine funobj
& ( mode, nnObj,
& x, fObj, gObj, nState,
& cu, lencu, iu, leniu, ru, lenru )

integer
& lencu, leniu, lenru, mode, nnObj, nState, iu(leniu)
double precision
& fObj, gObj(nnObj), ru(lenru), x(nnObj)
character
& cu(lencu)*8
```

On entry:

mode may be set as in funcon.

nnObj is the number of variables involved in $f_0(x)$ ($0 < \text{nnObj} \le n$). These must be the first nnObj variables in the problem.

x(nnObj) contains the nonlinear objective variables x. The array x must not be altered. nState is used as in funcon.

cu(lencu), iu(leniu), ru(lenru) are the same as in funcon.

On exit:

mode may be set as in funcon to indicate that you are unable to evaluate f_0 at x. If you wish to terminate the solution of the current problem, set mode ≤ -2 .

fObj must contain the computed value of $f_0(x)$ (except perhaps if mode = 1).

gObj(nnObj) must contain the known components of the gradient vector g(x), i.e., gObj(j) contains the partial derivative $\partial f_0/\partial x_j$ (except perhaps if mode = 0).

4.8. Example

Here we give the subroutines funobj and funcon for the example of Section 4.2, repeated here for convenience with generic variables x_j :

minimize
$$(x_1 + x_2 + x_3)^2 + 3x_3 + 5x_4$$

subject to $x_1^2 + x_2^2 + x_3 = 2$
 $x_2^4 + x_4 = 4$
 $2x_1 + 4x_2 \ge 0$

and $x_3 \ge 0$, $x_4 \ge 0$. This problem has 4 variables, 3 nonlinear objective variables, 2 nonlinear Jacobian variables, 2 nonlinear constraints and 1 linear constraint. The objective has some linear terms that we include as an extra "free row" (with infinite bounds). The calling program must assign

```
m = 4 n = 4 nnCon = 2 nnObj = 3 nnJac = 2 iObj = 4
```

Subroutine funobj works with the nonlinear objective variables (x_1, x_2, x_3) . Since x_3 occurs only linearly in the constraints, we have placed it *after* the Jacobian variables (x_1, x_2) .

For interest, we test mode to economize on gradient evaluations (even though they are cheap here). Note that Nonderivative linesearch would have to be specified, otherwise all entries would have mode = 2.

```
subroutine funobj
&
    ( mode, nnObj,
&
      x, f0bj, g0bj, nState,
&
      cu, lencu, iu, leniu, ru, lenru )
 integer
      mode, nnObj, nState, lencu, leniu, lenru, iu(leniu)
 double precision
      f0bj, x(nn0bj), g0bj(nn0bj), ru(lenru)
 character
      cu(lencu)*8
 Toy NLP problem from the SNOPT User's Guide.
 double precision
                 sum
       = x(1) + x(2) + x(3)
 sum
 if (mode .eq. 0 .or. mode .eq. 2) then
   f0bj
          = sum*sum
 end if
 if (mode .eq. 1 .or. mode .eq. 2) then
          = 2.0d + 0 * sum
   sum
   gObj(1) = sum
   gObj(2) = sum
   gObj(3) = sum
 end if
 end ! subroutine funobj
```

Subroutine funcon involves only (x_1, x_2) . First we treat the Jacobian as a *dense matrix*. In Fortran it is preferable to access two-dimensional arrays column-wise, as shown. Each column of gCon contains two elements, even though one of them is zero. The Acol, indA, locA data structure *must include these elements*, as well as other entries belonging to the linear constraints.

Since funcon is called before funobj, we test nState for the first and last entries.

```
subroutine funcon
   ( mode, nnCon, nnJac, neJac,
     x, fCon, gCon, nState,
     cu, lencu, iu, leniu, ru, lenru)
integer
&
     lencu, leniu, lenru, mode, neJac, nnCon, nnJac, nState,
double precision
     fCon(nnCon), gCon(nnCon,nnJac), ru(lenru), x(nnJac)
character
     cu(lencu)*8
Toy NLP problem with dense Jacobian.
integer
     nout
double precision
  x1, x2
nout = 9
x1
       = x(1)
x2
       = x(2)
if (nState .eq. 1) then
                           ! First entry
   if (nout .gt. 0) write(nout, '(/a)') ' This is problem Toy'
end if
if (mode .eq. 0 .or. mode .eq. 2) then
   fCon(1) = x1**2 + x2**2
   fCon(2) =
                       x2**4
end if
if (mode .ge. 1) then
   gCon(1,1) = 2.0d+0*x1
                             ! Jacobian elements for column 1
   gCon(2,1) = 0.0d+0
                             ! Can't be omitted
   gCon(1,2) = 2.0d+0*x2
                             ! Jacobian elements for column 2
   gCon(2,2) = 4.0d+0*x2**3
end if
if (nState .ge. 2) then
                             ! Last entry
   if (nout .gt. 0) write(nout, '(/a)') 'Finished problem Toy'
end if
end ! subroutine funcon
```

Now we treat the Jacobian as a sparse matrix, stored column-wise. Note that gCon has only 3 entries because we intentionally omit the zero entry in column 1. The first column of the Acol, indA, locA data structure must also have that entry deleted.

```

if (nState .ge. 2) then
                           ! Last entry
   if (nout .gt. 0) write(nout, '(/a)') 'Finished problem Toy'
end if
end ! subroutine funcon
```

4.9. Constant Jacobian elements

If all constraint gradients (Jacobian elements) are known (Derivative level = 2 or 3), any *constant* elements may be given to snOptB in the array Acol if desired. The Jacobian array gCon is initialized from the appropriate elements of Acol. If any are constant and have the correct value, funcon need not reassign them in gCon.

Note that constant *nonzero* elements do affect fCon. Thus, if J_{ij} is assigned correctly in a(*) and is constant, a linear term gCon(i,j)*x(j) or gCon(l)*x(j) must be added to fCon(i) (depending on whether gCon is a two- or one-dimensional array).

Remember, if Derivative level < 2, unassigned elements of gCon are *not* treated as constant—they are estimated by finite differences at significant expense.

4.10. Subroutine snMemB

This routine estimates the size of the workspace arrays cw, iw, rw required to solve an optimization problem of given dimensions. snMemB is not strictly needed in f77 because all workspace must be defined explicitly in the driver program at compile time. It is available for users wishing to allocate storage dynamically in f90 or C.

The actual storage required also depends on the values of the following options:

```
Hessian full

or Hessian limited memory and Hessian updates
Reduced Hessian dimension

Superbasics limit
```

If these options have not been set, default values are assumed. Ideally the correct values should be set *before* the call to snMemB.

```
subroutine snMemB
& ( INFO, m, n, neA, negCon,
& nnCon, nnJac, nnObj,
& mincw, miniw, minrw,
& cw, lencw, iw, leniw, rw, lenrw )

integer
& INFO, lencw, leniw, lenrw, m, mincw, miniw, minrw, n, neA,
& negCon, nnCon, nnJac, nnObj, iw(leniw)
double precision
& rw(lenrw)
character
& cw(lencw)*8
```

The arguments m, n, neA, nnCon, nnJac, nnObj define the problem being solved and are identical to the arguments used in the call to snOptB (see Section 4.4). For a sequence of problems, snMemB may be called once with overestimates of these quantities.

On entry:

```
negCon is the number of nonzeros in the Jacobian gCon (negCon \leq nnCon * nnJac). lencw, leniw, lenrw must be of length at least 500.
```

cw(lencw), iw(leniw), rw(lenrw) are 8-character, integer and real arrays of workspace
for snMemB.

On exit:

INFO reports the result of the call to snMemB. Here is a summary of possible values. Further details are in Section 8.6.

Insufficient storage allocated

81 work arrays must have at least 500 elements

Finished successfully

104 memory requirements estimated

mincw, miniw, minrw estimate how much character, integer and real storage is needed to solve the problem.

To use snMemB, the first step is to allocate the work arrays. These may be temporary arrays tmpcw, tmpiw, tmprw (say) or the snOptB arrays cw, iw, rw, which will be reallocated after the storage limits are known. Here we illustrate the use of snMemB using the same arrays for snMemB and snOptB. Note that the snMemB arrays are used to store the optional parameters, and so any temporary arrays must be copied into the final cw, iw, rw arrays in order to retain the options.

The work arrays must have length at least 500, so we define

```
ltmpcw = 500
ltmpiw = 500
ltmprw = 500
```

As with all SNOPT routines, $snInit\ must$ be called to initialize the optional parameters to their default values:

```
call snInit
& ( iPrint, iSumm, cw, ltmpcw, iw, ltmpiw, rw, ltmprw )
```

This installs ltmpcw, ltmprw as the default internal upper limits on the snOptB workspace (see the description of Total real workspace in Section 7.6). (They are used to compute the boundaries of any user-defined workspace in cw, iw or rw.)

The next step is to call snMemB to obtain mincw, miniw, minrw as estimates of the storage needed by snOptB:

```
call snMemB
& ( INFO, m, n, neA, negCon,
& nnCon, nnJac, nnObj,
& mincw, miniw, minrw,
& cw, ltmpcw, iw, ltmpiw, rw, ltmprw )
```

The output values of mincw, miniw, minrw may now be used to define the lengths of the snOptB work arrays:

```
lencw = mincw
leniw = miniw
lenrw = minrw
```

These values may be used in f90 or C to allocate the final work arrays for the problem.

One last step is needed before snOptB is called. The current upper limits ltmpcw, ltmpiw, ltmprw must be replaced by the estimates mincw, miniw, minrw. This is done using the option setting routine snSeti as follows:

```
Errors = 0
                          ! Counts the number of errors
iPrt = 0
                          ! Suppress print output
iSum = 0
                          ! Suppress summary output
call snSeti
& ('Total character workspace', lencw, iPrt, iSum, Errors,
     cw, ltmpcw, iw, ltmpiw, rw, ltmprw)
call snSeti
& ('Total integer workspace', leniw, iPrt, iSum, Errors,
     cw, ltmpcw, iw, ltmpiw, rw, ltmprw)
call snSeti
                      workspace', lenrw, iPrt, iSum, Errors,
   ( 'Total real
&
     cw, ltmpcw, iw, ltmpiw, rw, ltmprw )
```

An alternative way is to call snInit again with arguments lencw, leniw, lenrw:

```
call snInit
& ( iPrint, iSumm, cw, lencw, iw, leniw, rw, lenrw )
```

However, this has the twin effects of resetting all options to their default values, and reprinting the SNOPT banner (unless iPrint = 0 and iSumm = 0 are set for the PRINT and SUMMARY files).

5. The snOptC interface

The snOptC interface is identical to snOptB except that both objective and constraint functions are provided in a single routine usrfun instead of being computed separately in funobj and funcon. This arrangement may be more convenient when the objective and constraint functions depend on common data that is difficult to share between separate routines.

5.1. Subroutine snOptC

Problem (SparseNP) is solved by a call to subroutine snOptC, whose parameters are defined here. Note that most machines use double precision declarations as shown, but some machines use real. The same applies to the user routines funobj and funcon.

```
subroutine snOptC
    (Start, m, n, neA, nName,
      nnCon, nnObj, nnJac,
&
      iObj, ObjAdd, Prob,
&
&
      usrfun,
      Acol, indA, locA, bl, bu, Names,
Хr.
Хr.
      hs, x, pi, rc,
      INFO, mincw, miniw, minrw,
Хr.
Хr.
      nS, nInf, sInf, Obj,
&
      cu, lencu, iu, leniu, ru, lenru,
      cw, lencw, iw, leniw, rw, lenrw )
Хr.
 external
&
      usrfun
 integer
      INFO, iObj, lencu, leniu, lenru, lencw, leniw, lenrw,
&
      mincw, miniw, minrw, m, n, neA, nName, nS, nInf, nnCon,
&
      nnObj, nnJac, indA(neA), hs(n+m), locA(n+1), iu(leniu),
      iw(leniw)
double precision
      Obj, ObjAdd, sInf, Acol(neA), bl(n+m), bu(n+m), pi(m),
      rc(n+m), ru(lenru), rw(lenrw), x(n+m)
 character*(*)
      Start
&
 character
      Prob*8, Names(nName)*8, cu(lencu)*8, cw(lencw)*8
```

All arguments except usrfun are the same as those for the snOptB interface. The description of usrfun follows.

5.2. Subroutine usrfun

This subroutine must calculate the nonlinear problem functions $f_0(x)$ and f(x), and (optionally) their derivatives g(x) and f'(x).

The objective derivatives are stored in the output array gObj. Constraint derivatives are stored column-wise in the output array gCon. Recall that f'(x) is the top left corner of a larger matrix A that is stored column-wise in snOptB's input arrays Acol, indA, locA (see

(4.2) and Sections 4.3, 4.4). Jacobian elements must be stored in gCon in the same order as the corresponding parts of Acol, indA, locA.

For small problems (or large dense ones) it is convenient to treat the Jacobian as a dense matrix and declare gCon as a two-dimensional array gCon(*,*) (which is stored columnwise in Fortran). It is then simple to compute the Jacobian by rows or by columns. For problems with sparse Jacobians, it is essential to use a one-dimensional array gCon(*) in order to conserve storage. Thus, funcon should use just one of the declarations

```
double precision gCon(nnCon,nnJac) double precision gCon(neJac)
```

according to convenience.

```
subroutine usrfun
         ( mode, nnObj, nnCon, nnJac, nnL, neJac,
           x, fObj, gObj, fCon, gCon,
     &
           nState, cu, lencu, iu, leniu, ru, lenru )
      integer
           lencu, leniu, lenru, mode, nnObj, nnCon, nnJac, nnL, neJac,
           nState, iu(leniu)
      double precision
           fObj, fCon(nnCon), gObj(nnObj), ru(lenru), x(nnL)
      character
           cu(lencu)*8
*** Choose ONE of the following:
      double precision
                         gCon(nnCon,nnJac)
      double precision
                         gCon(neJac)
```

On entry:

mode indicates which combination of fCon, gCon, fObj and gObj, must be assigned during the present call of usrfun. snOptC will call usrfun with mode = 0, 1 or 2. You may test mode to decide what to do:

- If mode = 2, assign fObj, fCon and the known components of gObj and gCon.
- If mode = 1, assign the known components of gObj and gCon; fObj and fCon are not required and are ignored.
- If mode = 0, only fObj and fCon need be assigned; gObj and gCon are ignored.

nnObj is the number of variables involved in $f_0(x)$ ($0 < \text{nnObj} \le n$). These must be the first nnObj variables in the problem.

nnCon is the number of nonlinear constraints (nnCon > 0). These must be the first nnCon constraints in the problem.

nnJac is the number of variables involved in f(x) ($0 < \text{nnJac} \le n$). These must be the first nnJac variables in the problem.

nnL is max{nnObj, nnJac}, the number of nonlinear variables. These must be the first nnL variables in the problem.

x(nnL) contains the nonlinear variables x. The array x must not be altered.

neJac is the number of nonzero elements in gCon. If gCon is stored as a two-dimensional array, then $neJac = nnCon \times nnJac$.

x(nnJac) contains the nonlinear Jacobian variables x. The array x must not be altered. nState indicates the first and last calls to usrfun.

If nState = 0, there is nothing special about the current call to usrfun.

If nState = 1, snOptC is calling your subroutine for the *first* time. Some data may need to be input or computed and saved. Note that if there are nonlinear constraints, the first call to funcon will occur *before* the first call to funobj.

If $nState \geq 2$, snOptC is calling your subroutine for the *last* time. You may wish to perform some additional computation on the final solution. Note again that if there are nonlinear constraints, the last call to funcon will occur *before* the last call to funobj.

In general, the last call is made with nState = 2 + INFO, where INFO indicates the status of the final solution. In particular, if nState = 2, the current x is *optimal*; if nState = 3, the problem appears to be infeasible; if nState = 4, the problem appears to be unbounded; and if nState = 5, the iterations limit was reached. In some cases, the solution may be *nearly* optimal if nState = 11; this value occurs if the linesearch procedure was unable to find an improved point.

If the nonlinear functions are expensive to evaluate, it may be desirable to do nothing on the last call, by including a statement of the form

```
if (nState .ge. 2) return
```

at the start of the subroutine.

cu(lencu), iu(leniu), ru(lenru) are the character, integer and real arrays of user workspace provided to snOptC. They may be used to pass information into the function routines and to preserve data between calls.

In special applications the functions may depend on some of the internal variables stored in snOptC's workspace arrays cw, iw, rw. For example, the 8-character problem name Prob is stored in cw(51), and the dual variables are stored in rw(lxMul) onward, where lxMul = iw(316). These will be accessible to usrfun if snOptC is called with parameters cu, iu, ru the same as cw, iw, rw.

If you still require user workspace, elements

```
rw(501:maxru) and rw(maxrw+1:lenru)
```

are set aside for this purpose, where maxru = iw(2). Similarly for workspace in cw and rw. (See the Total and User workspace options.)

On exit:

mode may be used to indicate that you are unable or unwilling to evaluate the problem functions at the current x.

During the linesearch, the functions are evaluated at points of the form $x = x_k + \alpha p_k$ after they have already been evaluated satisfactorily at x_k . At any such α , if you set mode to -1, snOptC will evaluate the functions at some point closer to x_k (where they are more likely to be defined).

If for some reason you wish to terminate solution of the current problem, set mode to a negative value (other than -1).

- f0bj must contain the computed value of $f_0(x)$ (except perhaps if mode = 1).
- gObj(nnObj) must contain the known components of the gradient vector g(x), i.e., gObj(j) contains the partial derivative $\partial f_0/\partial x_j$ (except perhaps if mode = 0).
- fCon(nnCon) contains the computed constraint vector f(x) (except perhaps if mode = 1).
- gCon(nnCon,nnJac) or gCon(neJac) contains the computed Jacobian f'(x) (except perhaps if mode = 0).

These gradient elements must be stored in gCon in exactly the same positions as implied by the definitions of snOptC's arrays Acol, indA, locA. There is no internal check for consistency (except indirectly via the Verify option), so great care is essential.

6. The npOpt interface

The npOpt interface is designed for the solution of small dense problems. The calling sequences of npOpt and its associated user-defined functions are designed to be similar to those of the dense SQP code NPSOL (Gill et al.[9]). For the case of npOpt it is convenient to restate the problem (NPsparse) with the constraints reordered as:

(DenseNP)
$$\min_{x} f_{0}(x)$$
 subject to $l \leq \begin{pmatrix} x \\ A_{L}x \\ f(x) \end{pmatrix} \leq u$.

where l and u are constant lower and upper bounds, f_0 is a smooth scalar objective function, A_L is a matrix, and f(x) is a vector of smooth nonlinear constraint functions $\{f_i(x)\}$. The interface npOpt is designed to handle problems for which the objective and constraint gradients are dense, i.e., they do not have a significant number of elements that are identically zero.

A typical invocation of npOpt would be:

```
call npInit( iPrint, iSumm, ... )
call npSpec( ... )
call npOpt ( n, nclin, ncnln, ... )
```

where npSpec reads a file of optional parameter definitions.

Figure 1 illustrates the feasible region for the jth pair of constraints $\ell_j \leq r_j(x) \leq u_j$. The quantity δ is the optional parameter feasibility tolerance, which can be set by the user (see Section 7). The constraints $\ell_j \leq r_j \leq u_j$ are considered "satisfied" if r_j lies in Regions 2, 3 or 4, and "inactive" if r_j lies in Region 3. The constraint $r_j \geq \ell_j$ is considered "active" in Region 2, and "violated" in Region 1. Similarly, $r_j \leq u_j$ is active in Region 4, and violated in Region 5. For equality constraints $(\ell_j = u_j)$, Regions 2 and 4 are the same and Region 3 is empty.

Figure 1: Illustration of the constraints $\ell_j \leq r_j(x) \leq u_j$. The bounds ℓ_j and u_j are considered "satisfied" if $r_j(x)$ lies in Regions 2, 3 or 4, where δ is the feasibility tolerance. The constraints $r_j(x) \geq \ell_j$ and $r_j(x) \leq u_j$ are both considered "inactive" if $r_j(x)$ lies in Region 3.

6.1. Subroutines used by npOpt

npOpt is accessed via the following routines:

```
npInit (Section 1.6) Must be called before any other npOpt routines.
npSpec (Section 7.3) May be called to input a SPECS file (a list of run-time options).
npSet, npSeti, npSetr (Section 7.4) May be called to specify a single option.
npGet, npGetc, npGeti, npGetr (Section 7.5) May be called to obtain an option's current value.
funcon, funobj (Section 6.3) Supplied by the user and called by npOpt. They define the constraint functions f(x) and objective function fo(x).
npOpt (Section 6) The main solver.
npMem (In distribution file npO2lib.f) Computes the size of the workspace arrays iw and rw required for given problem dimensions. Intended for Fortran 90 drivers that reallocate workspace if necessary.
```

The user routines funcon and funobj have a fixed parameter list but may have any convenient name. They are passed to npOpt as parameters.

6.2. Subroutine npOpt

In the following specification of npOpt, we define r(x) as the vector of combined constraint functions $r(x) = (x \ A_L x \ f(x))$, and use nctotl to denote a variable that holds its dimension nctotl = n + nclin + ncnln. Note that most machines use double precision declarations as shown, but some machines use real. The same applies to the user routines funcon and funobj.

```
subroutine npOpt
    ( n, nclin, ncnln, ldA, ldg, ldH,
      A, bl, bu, funcon, funobj,
&
&
      INFO, majIts, iState,
      fCon, gCon, cMul, fObj, gObj, Hess, x,
&
      iw, leniw, rw, lenrw )
external
&
      funcon, funobj
integer
      INFO, ldA, ldg, ldH, leniw, lenrw, majIts, n, nclin,
      ncnln, iState(n+nclin+ncnln), iw(leniw)
double precision
Хr.
      fObj, A(ldA,*), bl(n+nclin+ncnln), bu(n+nclin+ncnln),
      cMul(n+nclin+ncnln), fCon(*), gCon(ldg,*), gObj(n),
&
      Hess(ldH,*), rw(lenrw), x(n)
&
```

On entry:

```
n is n, the number of variables in the problem (n > 0).
nclin is m_L, the number of general linear constraints (nclin > 0).
```

- ncnln is m_N , the number of nonlinear constraints (ncnln > 0).
- 1dA is the row dimension of the array A (1dA > 1, 1dA > nclin).
- ldg is the row dimension of the array gCon $(ldg \ge 1, ldg \ge ncnln)$.
- ldH is the row dimension of the array Hess (ldH \geq n).
- A is an array of dimension (1dA,k) for some $k \geq n$. It contains the matrix A_L for the linear constraints. If nclin = 0, A is not referenced. (In that case, A may be dimensioned (1dA,1) with 1dA = 1, or it could be any convenient array.)
- bl(nctotl), bu(nctotl) contain the lower and upper bounds for r(x) in problem (NP). To specify a non-existent lower bound $(\ell_j = -\infty)$, set $\operatorname{bl}(j) \leq -\inf \operatorname{Bnd}$, where $\inf \operatorname{Bnd}$ is the Infinite Bound, whose default value is 10^{20} . Similarly, a non-existent upper bound $(u_j = \infty)$, can be any $\operatorname{bu}(j) \geq \inf \operatorname{Bnd}$. To specify an equality constraint $(\operatorname{say} r_j(x) = \beta)$, set $\operatorname{bl}(j) = \operatorname{bu}(j) = \beta$, where $|\beta| < \inf \operatorname{Bnd}$.

For the data to be meaningful, it is required that $bl(j) \leq bu(j)$ for all j.

- funcon, funobj are the names of subroutines that calculate the nonlinear constraint functions f(x), the objective function $f_0(x)$ and (optionally) their gradients for a specified n-vector x. The arguments funcon and funobj must be declared as external in the routine that calls npOpt. For a detailed description of funcon and funobj, see Section 6.3.
- istate(nctotl) is an integer array that need not be initialized if npOpt is called with a Cold Start (the default option).

For a Warm start, every element of istate must be set. If npOpt has just been called on a problem with the same dimensions, istate already contains valid values. Otherwise, istate(j) should indicate whether either of the constraints $r_j(x) \ge \ell_j$ or $r_j(x) \le u_j$ is expected to be active at a solution of (DenseNP).

The ordering of istate is the same as for bl, bu and r(x), i.e., the first n components of istate refer to the upper and lower bounds on the variables, the next nclin refer to the bounds on $A_L x$, and the last ncnln refer to the bounds on f(x). Possible values for istate(j) follow.

- Neither $r_j(x) \ge \ell_j$ nor $r_j(x) \le u_j$ is expected to be active.
- 1 $r_j(x) \ge \ell_j$ is expected to be active.
- $r_j(x) \le u_j$ is expected to be active.
- This may be used if $\ell_j = u_j$. Normally an equality constraint $r_j(x) = \ell_j = u_j$ is active at a solution.

The values 1, 2 or 3 all have the same effect when bl(j) = bu(j). If necessary, npOpt will override the user's specification of istate, so that a poor choice will not cause the algorithm to fail.

gCon(ldg,*) is an array of dimension (ldg,k) for some $k \ge n$. If ncnln = 0, gCon is not referenced. (In that case, gCon may be dimensioned (ldg,1) with ldg = 1.)

In general, gCon need not be initialized before the call to npOpt. However, if Derivative level = 3, any constant elements of gCon may be initialized. Such elements need not be reassigned on subsequent calls to funcon (see Section 6.6).

cMul(nctotl) is an array that need not be initialized if npOpt is called with a Cold start (the default).

Otherwise, the ordering of cMul is the same as for bl, bu and istate. For a Warm start, the components of cMul corresponding to nonlinear constraints must contain a multiplier estimate. The sign of each multiplier should match istate as follows. If the ith nonlinear constraint is defined as "inactive" via the initial value istate(j) = 0, j = n + nclin + i, then cMul(j) should be zero. If the constraint $r_j(x) \geq \ell_j$ is active (istate(j) = 1), cMul(j) should be non-negative, and if $r_j(x) \leq u_j$ is active (istate(j) = 2), cMul(j) should be non-positive.

If necessary, npOpt will change cMul to match these rules.

- Hess(ldH,*) is an array of dimension (ldH,k) for some $k \geq n$. Hess need not be initialized if npOpt is called with a Cold Start (the default), and will be taken as the identity. For a Warm Start, Hess provides the initial approximation of the Hessian of the Lagrangian, i.e., $H(i,j) \approx \partial^2 \mathcal{L}(x,\lambda)/\partial x_i \partial x_j$, where $\mathcal{L}(x,\lambda) = f_0(x) f(x)^T \lambda$ and λ is an estimate of the optimal Lagrange multipliers. Hess must be a positive-definite matrix.
- x(n) is an initial estimate of the solution.
- iw(leniw), rw(lenrw) are integer and real arrays of workspace for npOpt.

Both leniw and lenrw must be at least 500. In general, leniw and lenrw should be as large as possible because it is uncertain how much storage will be needed for the basis factors. As an estimate, leniw should be about 100(m+n) or larger, and lenrw should be about 200(m+n) or larger.

Appropriate values may be obtained from a preliminary run with leniw = lenrw = 500. If Print level is positive, the required amounts of workspace are printed before npOpt terminates with INFO = 43 or 44.

On exit:

INFO reports the result of the call to npOpt. Here is a summary of possible values (for a detailed description, see Section 8.6):

Finished successfully

- 1 optimality conditions satisfied
- 2 feasible point found
- 3 requested accuracy could not be achieved

The problem appears to be infeasible

- 11 infeasible linear constraints
- 12 infeasible linear equalities
- 13 nonlinear infeasibilities minimized
- 14 infeasibilities minimized

The problem appears to be unbounded

- 21 unbounded objective
- 22 constraint violation limit reached

Resource limit error

- 31 iteration limit reached
- 32 major iteration limit reached
- 33 the superbasics limit is too small

Terminated after numerical difficulties

- 41 current point cannot be improved
- 42 singular basis
- 43 cannot satisfy the general constraints
- 44 ill-conditioned null-space basis

Error in the user-supplied functions

- 51 incorrect objective derivatives
- 52 incorrect constraint derivatives

Undefined user-supplied functions

- 61 undefined function at the first feasible point
- 62 undefined function at the initial point
- 63 unable to proceed into undefined region

User requested termination

- 71 terminated during function evaluation
- 74 terminated from monitor routine

Insufficient storage allocated

- 81 work arrays must have at least 500 elements
- 82 not enough character storage
- 83 not enough integer storage
- 84 not enough real storage

Input arguments out of range

- 91 invalid input argument
- 92 basis file dimensions do not match this problem

System error

- 141 wrong number of basic variables
- 142 error in basis package

iter is the number of major iterations performed.

- istate describes the status of the constraints $\ell \leq r(x) \leq u$ in problem (NP). For the jth lower or upper bound, j=1 to nctot1, the possible values of istate(j) are as follows (see Figure 1). δ is the appropriate feasibility tolerance.
 - -2 (Region 1) The lower bound is violated by more than δ .
 - -1 (Region 5) The upper bound is violated by more than δ .
 - 0 (Region 3) Both bounds are satisfied by more than δ .
 - 1 (Region 2) The lower bound is active (to within δ).
 - 2 (Region 4) The upper bound is active (to within δ).

Region	1	2	3	4	5	$2 \equiv 4$
istate(j)	-2	1	0	2	-1	3
Printed solution		LL	FR	UL	++	EQ

Figure 2: Labels used in the printed solution for the regions of Figure 1.

3 (Region 2 = Region 4) The bounds are equal and the equality constraint is satisfied (to within δ).

These values of **istate** are labeled in the printed solution according to the table in Figure 2.

fCon is an array of dimension at least ncnln. If ncnln = 0, fCon is not accessed, and may then be declared to be of dimension (1), or the actual parameter may be any convenient array. If ncnln > 0, fCon contains the values of the nonlinear constraint functions $f_i(x)$, i = 1: ncnln, at the final iterate.

gCon contains the Jacobian matrix of the nonlinear constraints at the final iterate, i.e., gCon(i,j) contains the partial derivative of the *i*th constraint function with respect to the *j*th variable, i = 1 : ncnln, j = 1 : n. (See the discussion of gCon under funcon in Section 6.5.)

cMul contains the QP multipliers from the last QP subproblem. cMul(j) should be non-negative if istate(j) = 1 and non-positive if istate(j) = 2.

fObj is the value of the objective $f_0(x)$ at the final iterate.

gObj(n) contains the objective gradient (or its finite-difference approximation) at the final iterate.

Hess(ldH,*) contains information about H, the Hessian of the Lagrangian. Hess is an estimate of the Hessian of the Lagrangian at x.

x contains the final estimate of the solution.

6.3. User-supplied subroutines for npOpt

The user must provide subroutines that define the objective function and nonlinear constraints. The objective function is defined by subroutine funobj, and the nonlinear constraints are defined by subroutine funcon. On every call, these subroutines must return appropriate values of the objective and nonlinear constraints in f0bj and fCon. The user should also provide the available partial derivatives. Any unspecified derivatives are approximated by finite differences; see Section 7 for a discussion of the optional parameter Derivative level. Just before either funobj or funcon is called, each element of the current gradient array g or gCon is initialized to a special value. On exit, any element that retains the given value is estimated by finite differences.

For maximum reliability, it is preferable for the user to provide *all* partial derivatives (see Chapter 8 of Gill, Murray and Wright [13], for a detailed discussion). If all gradients cannot be provided, it is similarly advisable to provide as many as possible. While developing the subroutines funobj and funcon, the Verify parameter (see Section 7) should be used to check the calculation of any known gradients.

6.4. Subroutine funobj

This subroutine must calculate the objective function $f_0(x)$ and (optionally) the gradient g(x).

```
subroutine funobj
& ( mode, n, x, f0bj, g0bj, nState )
integer
& mode, n, nState
double precision
& f0bj, x(n), g0bj(n)
```

On entry:

is set by npOpt to indicate which values are to be assigned during the call of funobj. If Derivative level = 1 or Derivative level = 3, then all components of the objective gradient are defined by the user and mode will always have the value 2. If some gradient elements are unspecified, npOpt will call funobj with mode = 0, 1 or 2.

- If mode = 2, assign fObj and the known components of gObj.
- If mode = 1, assign all available components of gObj; fObj is not required.
- If mode = 0, only fObj needs to be assigned; gObj is ignored.
- n is the number of variables, i.e., the dimension of x. The actual parameter n will always be the same Fortran variable as that input to npOpt, and must not be altered by funobj.
- $\mathbf{x}(\mathbf{n})$ is an array containing the values of the variables x for which f_0 must be evaluated. The array \mathbf{x} must not be altered by $\mathbf{funob}\,\mathbf{j}$.

nState allows the user to save computation time if certain data must be read or calculated only once. If nState = 1, npOpt is calling funobj for the first time. If there are nonlinear constraints, the first call to funcon will occur before the first call to funobj.

On exit:

mode may be used to indicate that you are unable or unwilling to evaluate the objective function at the current x. (Similarly for the constraint functions.)

During the linesearch, the functions are evaluated at points of the form $x = x_k + \alpha p_k$ after they have already been evaluated satisfactorily at x_k . At any such α , if you set mode to -1, npOpt will evaluate the functions at some point closer to x_k (where they are more likely to be defined).

If for some reason you wish to terminate solution of the current problem, set mode to a negative value (other than -1).

- fObj must contain the computed value of $f_0(x)$ (except perhaps if mode = 1).
- gObj must contain the assigned components of the gradient vector g(x), i.e., gObj(j) contains the partial derivative $\partial f_0(x)/\partial x_j$ (except perhaps if mode = 0).

6.5. Subroutine funcon

This subroutine must compute the nonlinear constraint functions $\{f_i(x)\}$ and (optionally) their derivatives. (A dummy subroutine funcon must be provided if there are no nonlinear constraints.) The *i*th row of the Jacobian gCon is the vector $(\partial f_i/\partial x_1, \partial f_i/\partial x_2, \ldots, \partial f_i/\partial x_n)$.

```
subroutine funcon
& ( mode, ncnln, n, ldg,
& needc, x, fCon, gCon, nState )

integer
& mode, ncnln, n, ldg, nState, needc(*)
double precision
& x(n), fCon(*), gCon(ldg,*)
```

On entry:

mode is set by npOpt to request values that must be assigned during each call of funcon. mode will always have the value 2 if all elements of the Jacobian are available, i.e., if Derivative level is either 2 or 3 (see Section 7). If some elements of gCon are unspecified, npOpt will call funcon with mode = 0, 1, or 2:

- If mode = 2, only the elements of fCon corresponding to positive values of needc need to be set (and similarly for the known components of gCon).
- If mode = 1, the known components of the rows of gCon corresponding to positive values in needc must be set. Other rows of gCon and the array fCon will be ignored.
- If mode = 0, the components of fCon corresponding to positive values in needc must be set. Other components and the array gCon are ignored.

ncnln is the number of nonlinear constraints, i.e., the dimension of fCon. The actual parameter ncnln is the same Fortran variable as that input to npOpt, and must not be altered by funcon.

n is the number of variables, i.e., the dimension of x. The actual parameter n is the same Fortran variable as that input to npOpt, and must not be altered by funcon.

ldg is the leading dimension of the array gCon ($ldg \ge 1$ and $ldg \ge ncnln$).

needc is an array of dimension at least ncnln containing the indices of the elements of fCon or gCon that must be evaluated by funcon. needc can be ignored if every constraint is provided.

x is an array of dimension at least n containing the values of the variables x for which the constraints must be evaluated. x must not be altered by funcon.

nState has the same meaning as for funobj.

On exit:

mode

fCon is an array of dimension at least ncnln that contains the appropriate values of the nonlinear constraint functions. If needc(i) is nonzero and mode = 0 or 2, the value of the *i*th constraint at x must be stored in fCon(i). (The other components of fCon are ignored.)

gCon is an array of declared dimension (1dg,k), where $k \ge n$. It contains the appropriate elements of the Jacobian evaluated at x. (See the discussion of mode and gCon above.)

mode may be set as in funobj.

6.6. Constant Jacobian elements

If all constraint gradients (Jacobian elements) are known (i.e., Derivative Level = 2 or 3, any constant elements may be assigned to gCon one time only at the start of the optimization. An element of gCon that is not subsequently assigned in funcon will retain its initial value throughout. Constant elements may be loaded into gCon either before the call to npOpt or during the the first call to funcon (signalled by the value nState = 1). The ability to preload constants is useful when many Jacobian elements are identically zero, in which case gCon may be initialized to zero and nonzero elements may be reset by funcon.

Note that constant *nonzero* elements do affect the values of the constraints. Thus, if gCon(i, j) is set to a constant value, it need not be reset in subsequent calls to funcon, but the value gCon(i, j)*x(j) must nonetheless be added to fCon(i).

It must be emphasized that, if Derivative level < 2, unassigned elements of gCon are not treated as constant; they are estimated by finite differences, at non-trivial expense.

7. Optional parameters

The performance of each SNOPT interface is controlled by a number of parameters or "options". Each option has a default value that should be appropriate for most problems. (The defaults are given in the next section.) For special situations it is possible to specify non-standard values for some or all of the options. This options may be defined in a file called a *SPECS file*, or may be defined in the calling program using a call to one of the option-setting routines snSet, snSeti and snSetr (see Section 7.4). At any stage of the computation, the current value of an optional parameter may be examined by calling one of the routines snGet, snGeti and snGetr (see Section 7.5).

7.1. The SPECS file

The specs file contains a list of option definitions, using data in the following general form:

Begin options

Iterations limit 500
Minor feasibility tolerance 1.0e-7
Solution Yes

End options

We call such data a SPECS file because it specifies various options. The file starts with the keyword Begin and ends with End. Each line specifies a single option in free format, using one or more items as follows:

- 1. A keyword (required for all options).
- 2. A phrase (one or more words) that qualifies the keyword (only for some options).
- 3. A *number* that specifies an integer or real value (only for some options). Such numbers may be up to 16 contiguous characters in Fortran 77's I, F, E or D formats, terminated by a space.

The items may be entered in upper or lower case or a mixture of both. Some of the keywords have synonyms, and certain abbreviations are allowed, as long as there is no ambiguity. Blank lines and comments may be used to improve readability. A comment begins with an asterisk (*), which may appear anywhere on a line. All subsequent characters on the line are ignored.

It may be useful to include a comment on the first (Begin) line of the file. This line is echoed to the SUMMARY file, and appears on the screen in an interactive environment.

Most of the options described in the next section should be left at their default values for any given model. If experimentation is necessary, we recommend changing just one option at a time.

7.2. SPECS file checklist and defaults

The following example SPECS file shows all valid *keywords* and their *default values*. The keywords are grouped according to the function they perform.

Some of the default values depend on ϵ , the relative precision of the machine being used. The values given here correspond to double-precision arithmetic on most current machines ($\epsilon \approx 2.22 \times 10^{-16}$). Similar values would apply to any machine having about 15 decimal digits of precision.

```

7.3. Subroutine snSpec

Subroutine snSpec may be called to input a SPECS file (to specify options for a subsequent call of SNOPT).

```
subroutine snSpec
& ( iSpecs, INFO, cw, lencw, iw, leniw, rw, lenrw )
  integer
&    iSpecs, INFO, lencw, leniw, lenrw, iw(leniw)
  double precision
&    rw(lenrw)
  character
&    cw(lencw)*8
```

On entry:

iSpecs is a unit number for the SPECS file (iSpecs > 0). Typically iSpecs = 4.

On some systems, the file may need to be opened before snSpec is called.

On exit:

```
cw(lencw), iw(leniw), rw(lenrw) contain the specified options.
```

INFO reports the result of the call to snSpec. Here is a summary of possible values. Further details are given in Section 8.6.

finished successfully

101 OPTIONS file read

errors while reading OPTIONS file

- 131 no OPTIONS file specified
- 132 End-of-file encountered while reading OPTIONS file
- 133 End-of-file encountered while looking for OPTIONS file
- 134 ENDRUN found before any valid OPTIONS
- > 134 there were i = INFO 134 errors while reading the OPTIONS file

7.4. Subroutines snSet, snSeti, snSetr

These routines specify a single option that might otherwise be defined in one line of a SPECS file.

```
subroutine snSet
    (buffer,
                      iPrint, iSumm, Errors,
                      cw. lencw. iw. leniw. rw. lenrw )
subroutine snSeti
    ( buffer, ivalue, iPrint, iSumm, Errors,
                      cw, lencw, iw, leniw, rw, lenrw )
subroutine snSetr
   (buffer, rvalue, iPrint, iSumm, Errors,
                      cw, lencw, iw, leniw, rw, lenrw)
Хr.
 character*(*)
      buffer
integer
      Errors, ivalue, iPrint, iSumm, lencw, leniw, lenrw, iw(leniw)
double precision
      rvalue, rw(lenrw)
 character
      cw(lencw)*8
```

On entry:

buffer is a string to be decoded. Use snSet if the string contains all relevant data. For example, if the value 1000 is known at compile time, say

```
call snSet ('Iterations 1000', iPrint, iSumm, Errors, ...) Restriction: len(buffer) \leq 72 (snSet) or \leq 55 (snSeti and snSetr).
```

ivalue is an integer value associated with the keyword in buffer. Use snSeti if it is convenient to define the value at run time. For example, the following allows the iterations limit to be computed:

```
itnlim = 1000
if (m .gt. 500) itnlim = 8000
call snSeti( 'Iterations', itnlim, iPrint, iSumm, Errors, ... )
```

rvalue is a real value associated with the keyword in buffer. The following illustrates how the LU stability tolerance could be defined at run time:

```
factol = 100.0d+0
if ( illcon ) factol = 5.0d+0
call snSetr( 'LU factor tol', factol, iPrint, iSumm, Errors, ... )
```

iPrint is a file number for printing each line of data, along with any error messages. iPrint = 0 suppresses this output.

iSumm is a file number for printing any error messages. iSumm = 0 suppresses this output.

Errors is the cumulative number of errors, so it should be 0 before the first call in a group of calls to option-setting routines.

On exit:

 ${\tt cw(lencw)}$, ${\tt iw(leniw)}$, ${\tt rw(lenrw)}$ record the specified option.

Errors is the number of errors encountered so far.

7.5. Subroutines snGet, snGetc, snGeti, snGetr

These routines obtain the current value of a single option.

```
integer function snGet
   (buffer,
                     Errors, cw, lencw, iw, leniw, rw, lenrw)
subroutine snGetc
   ( buffer, cvalue, Errors, cw, lencw, iw, leniw, rw, lenrw )
subroutine snGeti
   ( buffer, ivalue, Errors, cw, lencw, iw, leniw, rw, lenrw )
subroutine snGetr
   ( buffer, rvalue, Errors, cw, lencw, iw, leniw, rw, lenrw )
character*(*)
    buffer
integer
     Errors, ivalue, lencw, leniw, lenrw, iw(leniw)
character
     cvalue*8, cw(lencw)*8
double precision
    rvalue, rw(lenrw)
```

On entry:

buffer is a string to be decoded. Restriction: len(buffer) ≤ 72 .

Errors is the cumulative number of errors, so it should be 0 before the first call in a group of calls to option-getting routines.

On exit:

snGet is 1 if the option contained in buffer has been set, otherwise 0. Use snGet to find if a particular optional parameter has been set. For example: if

```
i = snGet( 'Hessian limited memory', Errors, ... )
```

then i will be 1 if SNOPT is using a limited-memory approximate Hessian.

cvalue is a string associated with the keyword in buffer. Use snGetc to obtain the names associated with an MPS file. For example, for the name of the bounds section use

```
call snGetc( 'Bounds', MyBounds, Errors, ... )
```

ivalue is an integer value associated with the keyword in buffer. Example:

```
call snGeti( 'Iterations limit', itnlim, Errors, ... )
```

rvalue is a real value associated with the keyword in buffer. Example:

```
call snGetr( 'LU factor tol', factol, Errors, ... )
```

Errors is the number of errors encountered so far.

cw(lencw), iw(leniw), rw(lenrw) contain the required option value.

7.6. Description of the optional parameters

The following is an alphabetical list of the options that may appear in the SPECS file, and a description of their effect. In the description of the options we use the notation of the problem format SparseNP to refer to the objective and constraint functions.

Backup Basis file i Default = 0

This is intended as a safeguard against losing the results of a long run. Suppose that a NEW BASIS file is being saved every 100 iterations, and that SNOPT is about to save such a basis at iteration 2000. It is conceivable that the run may be interrupted during the next few milliseconds (in the middle of the save). In this case the basis file will be corrupted and the run will have been essentially wasted.

To eliminate this risk, both a NEW BASIS file and a BACKUP BASIS file may be specified. The following would be suitable for the above example:

OLD BASIS file	11	(or 0)
BACKUP BASIS file	11	
NEW BASIS file	12	
Save frequency	100	

The current basis will then be saved every 100 iterations, first on file 12 and then immediately on file 11. If the run is interrupted at iteration 2000 during the save on file 12, there will still be a usable basis on file 11 (corresponding to iteration 1900).

Note that a NEW BASIS will be saved at the end of a run if it terminates normally, but there is no need for a further BACKUP BASIS. In the above example, if an optimum solution is found at iteration 2050 (or if the iteration limit is 2050), the final basis on file 12 will correspond to iteration 2050, but the last basis saved on file 11 will be the one for iteration 2000.

Central difference interval r Default $= \epsilon^{1/3} \approx 6.0$ e-6

When Derivative option = 0 with the snOptA interface, or Derivative level < 3) with snOptB or snOptC, the central-difference interval r is used near an optimal solution to obtain more accurate (but more expensive) estimates of gradients. Twice as many function evaluations are required compared to forward differencing. The interval used for the jth variable is $h_j = r(1 + |x_j|)$. The resulting derivative estimates should be accurate to $O(r^2)$, unless the functions are badly scaled.

Check frequency i Default = 60

Every *i*th minor iteration after the most recent basis factorization, a numerical test is made to see if the current solution x satisfies the general linear constraints (including linearized nonlinear constraints, if any). The constraints are of the form Ax - s = b, where s is the set of slack variables. To perform the numerical test, the residual vector r = b - Ax + s is computed. If the largest component of r is judged to be too large, the current basis is refactorized and the basic variables are recomputed to satisfy the general constraints more accurately.

Check frequency 1 is useful for debugging purposes, but otherwise this option should not be needed.

 $\begin{array}{ll} {\rm Crash\ option} & i & {\rm Default} = 3 \\ {\rm Crash\ tolerance} & r & {\rm Default} = 0.1 \end{array}$

Except on restarts, a CRASH procedure is used to select an initial basis from certain rows and columns of the constraint matrix (A - I). The Crash option i determines which rows and columns of A are eligible initially, and how many times CRASH is called. Columns of -I are used to pad the basis where necessary.

- i Meaning
- 0 The initial basis contains only slack variables: B = I.
- 1 CRASH is called once, looking for a triangular basis in all rows and columns of the matrix A.
- 2 CRASH is called twice (if there are nonlinear constraints). The first call looks for a triangular basis in linear rows, and the iteration proceeds with simplex iterations until the linear constraints are satisfied. The Jacobian is then evaluated for the first major iteration and CRASH is called again to find a triangular basis in the nonlinear rows (retaining the current basis for linear rows).
- 3 CRASH is called up to three times (if there are nonlinear constraints). The first two calls treat *linear equalities* and *linear inequalities* separately. As before, the last call treats nonlinear rows before the first major iteration.

If $i \geq 1$, certain slacks on inequality rows are selected for the basis first. (If $i \geq 2$, numerical values are used to exclude slacks that are close to a bound.) CRASH then makes several passes through the columns of A, searching for a basis matrix that is essentially triangular. A column is assigned to "pivot" on a particular row if the column contains a suitably large element in a row that has not yet been assigned. (The pivot elements ultimately form the diagonals of the triangular basis.) For remaining unassigned rows, slack variables are inserted to complete the basis.

The Crash tolerance r allows the starting procedure CRASH to ignore certain "small" nonzeros in each column of A. If a_{\max} is the largest element in column j, other nonzeros a_{ij} in the column are ignored if $|a_{ij}| \leq a_{\max} \times r$. (To be meaningful, r should be in the range $0 \leq r < 1$.)

When r > 0.0, the basis obtained by CRASH may not be strictly triangular, but it is likely to be nonsingular and almost triangular. The intention is to obtain a starting basis containing more columns of A and fewer (arbitrary) slacks. A feasible solution may be reached sooner on some problems.

For example, suppose the first m columns of A are the matrix shown under LU factor tolerance; i.e., a tridiagonal matrix with entries -1, 4, -1. To help CRASH choose all m columns for the initial basis, we would specify Crash tolerance r for some value of r > 1/4.

Derivative level i Default = 3

This keyword is used by the snOptB, snOptC and npOpt interfaces. It should not be used when calling snOptA. The keyword Derivative level specifies which nonlinear function gradients are known analytically and will be supplied to SNOPT by the user subroutines funobj and funcon.

i Meaning

- 3 All objective and constraint gradients are known.
- 2 All constraint gradients are known, but some or all components of the objective gradient are unknown.
- 1 The objective gradient is known, but some or all of the constraint gradients are unknown.
- O Some components of the objective gradient are unknown and some of the constraint gradients are unknown.

The value i = 3 should be used whenever possible. It is the most reliable and will usually be the most efficient.

If i = 0 or 2, SNOPT will estimate the missing components of the objective gradient, using finite differences. This may simplify the coding of subroutine funobj. However, it could increase the total run-time substantially (since a special call to funobj is required for each missing element), and there is less assurance that an acceptable solution will be located. If the nonlinear variables are not well scaled, it may be necessary to specify a nonstandard Difference interval (see below).

If i = 0 or 1, SNOPT will estimate missing elements of the Jacobian. For each column of the Jacobian, one call to funcon is needed to estimate all missing elements in that column, if any. If Jacobian = sparse and the sparsity pattern of the Jacobian happens to be

where * indicates known gradients and ? indicates unknown elements, SNOPT will use one call to funcon to estimate the missing element in column 2, and another call to estimate both missing elements in column 3. No calls are needed for columns 1 and 4.

At times, central differences are used rather than forward differences. Twice as many calls to funobj and funcon are then needed. (This is not under the user's control.)

Derivative linesearch Nonderivative linesearch

Default

At each major iteration a line search is used to improve the merit function. A Derivative linesearch uses safeguarded cubic interpolation and requires both function and gradient values to compute estimates of the step α_k . If some analytic derivatives are not provided, or a Nonderivative linesearch is specified, SNOPT employs a line search based upon safeguarded quadratic interpolation, which does not require gradient evaluations.

A nonderivative line search can be slightly less robust on difficult problems, and it is recommended that the default be used if the functions and derivatives can be computed at approximately the same cost. If the gradients are very expensive relative to the functions, a nonderivative line search may give a significant decrease in computation time.

If Nonderivative linesearch is selected, snOptA signals the evaluation of the line search by calling usrfun with needG = 0. Once the line search is completed, the problem functions are called again with needF = 0 and needG = 0. If the potential savings provided by a nonderivative line search are to be realized, it is essential that usrfun be coded so that the derivatives are not computed when needG = 0.

The selection of Nonderivative linesearch for snOptB means that funobj and funcon are called with mode = 0 in the line search. Once the linesearch is completed, the problem

functions are called again with mode = 2. If the potential savings provided by a nonderivative linesearch are to be realized, it is essential that funobj and funcon be coded so that the derivatives are not computed when mode = 0.

Derivative option

i

Default = 1

This option is intended for snOptA only and should not be used with any other interface. The Derivative option specifies which nonlinear function gradients are known analytically and will be supplied to snOptA by the user subroutine usrfun.

- i Meaning
- 0 Some problem derivatives are unknown.
- 1 All problem derivatives are known.

The value i = 1 should be used whenever possible. It is the most reliable and will usually be the most efficient.

If i = 0 snOptA will estimate the missing components of G(x) using finite differences. This may simplify the coding of subroutine usrfun. However, it could increase the total runtime substantially (since a special call to usrfun is required for each column of the Jacobian that has a missing element), and there is less assurance that an acceptable solution will be located. If the nonlinear variables are not well scaled, it may be necessary to specify a nonstandard Difference interval (see below).

For each column of the Jacobian, one call to usrfun is needed to estimate all missing elements in that column, if any. If the sparsity pattern of the Jacobian happens to be

where * indicates known derivatives and ? indicates unknown elements, snOptA will use one call to usrfun to estimate the missing element in column 2, and another call to estimate both missing elements in column 3. No calls are needed for columns 1 and 4.

At times, central differences are used rather than forward differences. Twice as many calls to usrfun are then needed. (This is not under the user's control.)

Difference interval

h

Default = $\epsilon^{1/2} \approx 1.5$ e-8

This alters the interval h_1 that is used to estimate gradients by forward differences in the following circumstances:

- In the initial ("cheap") phase of verifying the problem derivatives.
- For verifying the problem derivatives.
- For estimating missing derivatives.

In all cases, a derivative with respect to x_j is estimated by perturbing that component of x to the value $x_j + h_1(1 + |x_j|)$, and then evaluating $f_0(x)$ or f(x) at the perturbed point. The resulting gradient estimates should be accurate to $O(h_1)$ unless the functions are badly scaled. Judicious alteration of h_1 may sometimes lead to greater accuracy.

If i > 0, the last solution obtained will be output to the file with unit number i in the format described in Section 9.3.

Default

Elastic mode No
Elastic mode Yes

Normally SNOPT initiates elastic mode only when it seems necessary. Option Yes causes elastic mode to be entered from the beginning.

Elastic weight ω Default = 10^4

This keyword determines the initial weight γ associated with problem NP(γ) on p. 8.

At major iteration k, if elastic mode has not yet started, a scale factor $\sigma_k = 1 + \|g(x_k)\|_{\infty}$ is defined from the current objective gradient. Elastic mode is then started if the QP subproblem is infeasible, or the QP dual variables are larger in magnitude than $\sigma_k \omega$. The QP is re-solved in elastic mode with $\gamma = \sigma_k \omega$.

Thereafter, major iterations continue in elastic mode until they converge to a point that is optimal for problem NP(γ). If the point is feasible for SparseNP (v=w=0), it is declared locally optimal. Otherwise, γ is increased by a factor of 10 and major iterations continue. If γ has already reached a maximum allowable value, SparseNP is declared locally infeasible.

Expand frequency i Default = 10000

This option is part of the EXPAND anti-cycling procedure [11] designed to make progress even on highly degenerate problems.

For linear models, the strategy is to force a positive step at every iteration, at the expense of violating the bounds on the variables by a small amount. Suppose that the Minor feasibility tolerance is δ . Over a period of i iterations, the tolerance actually used by SNOPT increases from 0.5δ to δ (in steps of $0.5\delta/i$).

For nonlinear models, the same procedure is used for iterations in which there is only one superbasic variable. (Cycling can occur only when the current solution is at a vertex of the feasible region.) Thus, zero steps are allowed if there is more than one superbasic variable, but otherwise positive steps are enforced.

Increasing i helps reduce the number of slightly infeasible nonbasic variables (most of which are eliminated during a resetting procedure). However, it also diminishes the freedom to choose a large pivot element (see Pivot tolerance).

Factorization frequency k Default = 50

At most k basis changes will occur between factorizations of the basis matrix.

- With linear programs, the basis factors are usually updated every iteration. The default k is reasonable for typical problems. Higher values up to k = 100 (say) may be more efficient on problems that are extremely sparse and well scaled.
- When the objective function is nonlinear, fewer basis updates will occur as an optimum is approached. The number of iterations between basis factorizations will therefore increase. During these iterations a test is made regularly (according to the Check frequency) to ensure that the general constraints are satisfied. If necessary the basis will be refactorized before the limit of k updates is reached.

Feasibility tolerance see Minor feasibility tolerance

Default = 1.0e-6

Feasible point see Minimize

Function precision

 ϵ_R

t

Default = $\epsilon^{0.8} \approx 3.7 \mathrm{e}$ -11

The relative function precision ϵ_R is intended to be a measure of the relative accuracy with which the nonlinear functions can be computed. For example, if f(x) is computed as 1000.56789 for some relevant x and if the first 6 significant digits are known to be correct, the appropriate value for ϵ_R would be 1.0e-6.

(Ideally the functions f(x) or $F_i(x)$ should have magnitude of order 1. If all functions are substantially less than 1 in magnitude, ϵ_R should be the absolute precision. For example, if f(x)=1.23456789e-4 at some point and if the first 6 significant digits are known to be correct, the appropriate value for ϵ_R would be 1.0e-10.)

• The default value of ϵ_R is appropriate for simple analytic functions.

i

• In some cases the function values will be the result of extensive computation, possibly involving an iterative procedure that can provide rather few digits of precision at reasonable cost. Specifying an appropriate Function precision may lead to savings, by allowing the line search procedure to terminate when the difference between function values along the search direction becomes as small as the absolute error in the values.

Hessian dimension see Reduced Hessian dimension

Default = $\min\{1000, n_1 + 1\}$

Hessian full memory Hessian limited memory

Default = Full if $n_1 < 75$

These options select the method for storing and updating the approximate Hessian. (SNOPT uses a quasi-Newton approximation to the Hessian of the Lagrangian. A BFGS update is applied after each major iteration.)

If Hessian full memory is specified, the approximate Hessian is treated as a dense matrix and the BFGS updates are applied explicitly. This option is most efficient when the number of nonlinear variables n_1 is not too large (say, less than 75). In this case, the storage requirement is fixed and one can expect 1-step Q-superlinear convergence to the solution.

Hessian limited memory should be used on problems where n_1 is very large. In this case a limited-memory procedure is used to update a diagonal Hessian approximation H_r a limited number of times. (Updates are accumulated as a list of vector pairs. They are discarded at regular intervals after H_r has been reset to their diagonal.)

Hessian frequency

Default = 9999999

If Hessian Full is selected and i BFGS updates have already been carried out, the Hessian approximation is reset to the identity matrix. (For certain problems, occasional resets may improve convergence, but in general they should not be necessary.)

Hessian Full memory and Hessian frequency = 20 have a similar effect to Hessian Limited memory and Hessian updates = 20 (except that the latter retains the current diagonal during resets).

Hessian updates i Default = 20

If Hessian Limited memory is selected and i BFGS updates have already been carried out, all but the diagonal elements of the accumulated updates are discarded and the updating process starts again.

Broadly speaking, the more updates stored, the better the quality of the approximate Hessian. However, the more vectors stored, the greater the cost of each QP iteration. The default value is likely to give a robust algorithm without significant expense, but faster convergence can sometimes be obtained with significantly fewer updates (e.g., i = 5).

Insert file f Default = 0

If f > 0, this references a file containing basis information in the format of Section 9.2.

- The file will usually have been output previously as a PUNCH file.
- The file will not be accessed if an OLD BASIS file is specified.

Infinite bound size r Default = 1.0e+20

If r > 0, r defines the "infinite" bound infBnd in the definition of the problem constraints. Any upper bound greater than or equal to infBnd will be regarded as plus infinity (and similarly for a lower bound less than or equal to -infBnd). If $r \le 0$, the default value is used.

Iterations limit k Default = max{10000, 20m}

This is the maximum number of minor iterations allowed (i.e., iterations of the simplex method or the QP algorithm), summed over all major iterations.

Linesearch tolerance t Default = 0.9

This controls the accuracy with which a steplength will be located along the direction of search each iteration. At the start of each line search a target directional derivative for the merit function is identified. This parameter determines the accuracy to which this target value is approximated.

- t must be a real value in the range $0.0 \le t \le 1.0$.
- The default value t = 0.9 requests just moderate accuracy in the line search.
- If the nonlinear functions are cheap to evaluate, a more accurate search may be appropriate; try t = 0.1, 0.01 or 0.001. The number of major iterations might decrease.
- If the nonlinear functions are expensive to evaluate, a less accurate search may be appropriate. If all gradients are known, try t=0.99. (The number of major iterations might increase, but the total number of function evaluations may decrease enough to compensate.)

• If not all gradients are known, a moderately accurate search remains appropriate. Each search will require only 1–5 function values (typically), but many function calls will then be needed to estimate missing gradients for the next iteration.

Load file f Default = 0

If f > 0, this references a file containing basis information in the format of Section 9.3.

- The file will usually have been output previously as a DUMP file.
- The file will not be accessed if an OLD BASIS file or an INSERT file is specified.

Log frequency k Default = 100 see Print frequency

LU factor tolerance r_1 Default = 100.0 (LP) or 3.99 (NLP) LU update tolerance r_2 Default = 10.0 (LP) or 3.99 (NLP)

These tolerances affect the stability and sparsity of the basis factorization B = LU during refactorization and updating, respectively. They must satisfy r_1 , $r_2 \ge 1.0$. The matrix L is a product of matrices of the form

 $\begin{pmatrix} 1 \\ \mu & 1 \end{pmatrix}$,

where the multipliers μ satisfy $|\mu| \leq r_i$. Smaller values of r_i favor stability, while larger values favor sparsity. The default values usually strike a good compromise.

- For large and relatively dense problems, $r_1 = 5.0$ (say) may give a useful improvement in stability without impairing sparsity to a serious degree.
- For certain very regular structures (e.g., band matrices) it may be necessary to reduce r_1 and/or r_2 in order to achieve stability. For example, if the columns of A include a submatrix of the form

$$\begin{pmatrix} 4 & -1 & & & & \\ -1 & 4 & -1 & & & & \\ & -1 & 4 & -1 & & & \\ & & \ddots & \ddots & \ddots & \\ & & & -1 & 4 & -1 \\ & & & & -1 & 4 \end{pmatrix},$$

both r_1 and r_2 should be in the range $1.0 \le r_i < 4.0$.

LU Partial Pivoting

Default

LU Rook Pivoting

LU Complete Pivoting

The LU factorization implements a Markowitz-type search for a pivot that locally minimizes the fill-in subject to a threshhold pivoting stability criterion. The default option is to use threshold partial pivoting. The options LU rook pivoting and LU complete pivoting are more expensive than partial pivoting but are more stable and better at revealing rank. LU complete pivoting is the default for the npOpt interface.

LU density tolerance
$$r_1$$
 Default $= 0.6$ LU singularity tolerance r_2 Default $= \epsilon^{2/3} \approx 3.2 \text{e}-11$

The density tolerance r_1 is used during LU factorization of the basis matrix. Columns of L and rows of U are formed one at a time, and the remaining rows and columns of the basis are altered appropriately. At any stage, if the density of the remaining matrix exceeds r_1 , the Markowitz strategy for choosing pivots is terminated. The remaining matrix is factored by a dense LU procedure. Raising the density tolerance towards 1.0 may give slightly sparser LU factors, with a slight increase in factorization time.

The singularity tolerance r_2 helps guard against ill-conditioned basis matrices. When the basis is refactorized, the diagonal elements of U are tested as follows: if $|U_{jj}| \leq r_2$ or $|U_{jj}| < r_2 \max_i |U_{ij}|$, the jth column of the basis is replaced by the corresponding slack variable. (This is most likely to occur after a restart, or at the start of a major iteration.)

In some cases, the Jacobian matrix may converge to values that make the basis exactly singular. (For example, a whole row of the Jacobian could be zero at an optimal solution.) Before exact singularity occurs, the basis could become very ill-conditioned and the optimization could progress very slowly (if at all). Setting a larger tolerance $r_2 = 1.0e-5$, say, may help cause a judicious change of basis.

Major feasibility tolerance
$$\epsilon_r$$
 Default = 1.0e-6

This specifies how accurately the nonlinear constraints should be satisfied. The default value of 1.0e-6 is appropriate when the linear and nonlinear constraints contain data to about that accuracy.

Let rowerr be the maximum nonlinear constraint violation, normalized by the size of the solution. It is required to satisfy

$$rowerr = \max_{i} \ viol_{i}/\|x\| \le \epsilon_{r}, \tag{7.1}$$

where $viol_i$ is the violation of the *i*th nonlinear constraint (i = 1 : nnCon).

In the major iteration log, rowerr appears as the quantity labeled "Feasibl". If some of the problem functions are known to be of low accuracy, a larger Major feasibility tolerance may be appropriate.

Major optimality tolerance
$$\epsilon_d$$
 Default = 1.0e-6

This specifies the final accuracy of the dual variables. On successful termination, SNOPT will have computed a solution (x, s, π) such that

$$\max \mathtt{Comp} = \max_{j} \ \mathtt{Comp}_{j} / \|\pi\| \ \leq \ \epsilon_{d}, \tag{7.2}$$

where Comp_j is an estimate of the complementarity slackness for variable j (j=1:n+m). The values Comp_j are computed from the final QP solution using the reduced gradients $d_j = g_j - \pi^T a_j$ (where g_j is the jth component of the objective gradient, a_j is the associated column of the constraint matrix (A-I), and π is the set of QP dual variables):

$$\operatorname{Comp}_j = \left\{ \begin{array}{ll} d_j \min\{x_j - l_j, 1\} & \text{if } d_j \ge 0; \\ -d_j \min\{u_j - x_j, 1\} & \text{if } d_j < 0. \end{array} \right.$$

In the major iteration log, maxComp appears as the quantity labeled "Optimal".

Major iterations limit

k

 $Default = \max\{1000, m\}$

This is the maximum number of major iterations allowed. It is intended to guard against an excessive number of linearizations of the constraints.

Major print level

p

Default = 00001

This controls the amount of output to the PRINT and SUMMARY files each major iteration. Major print level 1 gives normal output for linear and nonlinear problems, and Major print level 11 gives addition details of the Jacobian factorization that commences each major iteration.

In general, the value being specified may be thought of as a binary number of the form

Major print level JFDXbs

where each letter stands for a digit that is either 0 or 1 as follows:

- s a single line that gives a summary of each major iteration. (This entry in JFDXbs is not strictly binary since the summary line is printed whenever JFDXbs ≥ 1).
- b BASIS statistics, i.e., information relating to the basis matrix whenever it is refactorized. (This output is always provided if JFDXbs ≥ 10).
- $X x_k$, the nonlinear variables involved in the objective function or the constraints.
- D π_k , the dual variables for the nonlinear constraints.
- F $F(x_k)$, the values of the nonlinear constraint functions.
- J $J(x_k)$, the Jacobian matrix.

To obtain output of any items JFDXbs, set the corresponding digit to 1, otherwise to 0.

If J=1, the Jacobian matrix will be output column-wise at the start of each major iteration. Column j will be preceded by the value of the corresponding variable x_j and a key to indicate whether the variable is basic, superbasic or nonbasic. (Hence if J=1, there is no reason to specify X=1 unless the objective contains more nonlinear variables than the Jacobian.) A typical line of output is

3 1.250000D+01 BS

1 1.00000E+00

4 2.00000E+00

which would mean that x_3 is basic at value 12.5, and the third column of the Jacobian has elements of 1.0 and 2.0 in rows 1 and 4.

Major print level 0 suppresses most output, except for error messages.

Major step limit

r

Default = 2.0

This parameter limits the change in x during a line search. It applies to all nonlinear problems, once a "feasible solution" or "feasible subproblem" has been found.

- 1. A line search determines a step α over the range $0 < \alpha \le \beta$, where β is 1 if there are nonlinear constraints, or the step to the nearest upper or lower bound on x if all the constraints are linear. Normally, the first steplength tried is $\alpha_1 = \min(1, \beta)$.
- 2. In some cases, such as $f(x) = ae^{bx}$ or $f(x) = ax^b$, even a moderate change in the components of x can lead to floating-point overflow. The parameter r is therefore used to define a limit $\bar{\beta} = r(1 + ||x||)/||p||$ (where p is the search direction), and the first evaluation of f(x) is at the potentially smaller steplength $\alpha_1 = \min(1, \bar{\beta}, \beta)$.

- 3. Wherever possible, upper and lower bounds on x should be used to prevent evaluation of nonlinear functions at meaningless points. The Major step limit provides an additional safeguard. The default value r=2.0 should not affect progress on well behaved problems, but setting r=0.1 or 0.01 may be helpful when rapidly varying functions are present. A "good" starting point may be required. An important application is to the class of nonlinear least-squares problems.
- 4. In cases where several local optima exist, specifying a small value for r may help locate an optimum near the starting point.

Minimize Default

Maximize

Feasible point

The keywords Minimize and Maximize specify the required direction of optimization. It applies to both linear and nonlinear terms in the objective.

The keyword feasible point means "Ignore the objective function" while finding a feasible point for the linear and nonlinear constraints. It can be used to check that the nonlinear constraints are feasible without altering the call to SNOPT.

Minor iterations limit k Default = 500

If the number of minor iterations for the optimality phase of the QP subproblem exceeds k, then all nonbasic QP variables that have not yet moved are frozen at their current values and the reduced QP is solved to optimality.

Note that more than k minor iterations may be necessary to solve the reduced QP to optimality. These extra iterations are necessary to ensure that the terminated point gives a suitable direction for the line search.

In the major iteration log, a t at the end of a line indicates that the corresponding QP was artificially terminated using the limit k.

Note that Iterations limit defines an independent *absolute* limit on the *total* number of minor iterations (summed over all QP subproblems).

Minor feasibility tolerance t Default = 1.0e-6

SNOPT tries to ensure that all variables eventually satisfy their upper and lower bounds to within the tolerance t. This includes slack variables. Hence, general linear constraints should also be satisfied to within t.

Feasibility with respect to nonlinear constraints is judged by the Major feasibility tolerance (not by t).

- If the bounds and linear constraints cannot be satisfied to within t, the problem is declared *infeasible*. Let sInf be the corresponding sum of infeasibilities. If sInf is quite small, it may be appropriate to raise t by a factor of 10 or 100. Otherwise, some error in the data should be suspected.
- Nonlinear functions will be evaluated only at points that satisfy the bounds and linear constraints. If there are regions where a function is undefined, every attempt should be made to eliminate these regions from the problem.
 - For example, if $f(x) = \sqrt{x_1} + \log x_2$, it is essential to place lower bounds on both variables. If t = 1.0e-6, the bounds $x_1 \ge 10^{-5}$ and $x_2 \ge 10^{-4}$ might be appropriate. (The log singularity is more serious. In general, keep x as far away from singularities as possible.)

- If Scale option ≥ 1 , feasibility is defined in terms of the *scaled* problem (since it is then more likely to be meaningful).
- In reality, SNOPT uses t as a feasibility tolerance for satisfying the bounds on x and s in each QP subproblem. If the sum of infeasibilities cannot be reduced to zero, the QP subproblem is declared infeasible. SNOPT is then in *elastic mode* thereafter (with only the linearized nonlinear constraints defined to be elastic). See the Elastic options.

Minor print level

k

Default = 1

This controls the amount of output to the PRINT and SUMMARY files during solution of the QP subproblems. The value of k has the following effect:

- 0 No minor iteration output except error messages.
- ≥ 1 A single line of output each minor iteration (controlled by Print frequency and Summary frequency).
- ≥ 10 Basis factorization statistics generated during the periodic refactorization of the basis (see Factorization frequency). Statistics for the *first factorization* each major iteration are controlled by the Major print level.

New basis file

f

Default = 0

If f > 0, a basis map will be saved on file f every kth iteration, where k is the Save frequency.

The first line of the file will contain the word Proceeding if the run is still in progress. At the end of a run a further basis map will be saved, with some other word indicating the final solution status.

New superbasics limit

i

Default = 99

This option causes early termination of the QP subproblems if the number of free variables has increased significantly since the first feasible point. If the number of new superbasics is greater than i the nonbasic variables that have not yet moved are frozen and the resulting smaller QP is solved to optimality.

In the major iteration log, a "T" at the end of a line indicates that the QP was terminated early in this way.

Old basis file

f

Default = 0

If f > 0, the starting point will be obtained from this file in the format of Section 9.1.

The file will usually have been output previously as a New Basis file. It will not be acceptable if the number of rows or columns in the problem has been altered.

Partial price

i

Default = 10 (LP) or 1 (NLP)

This parameter is recommended for large problems that have significantly more variables than constraints. It reduces the work required for each "pricing" operation (when a nonbasic variable is selected to become superbasic).

• When i = 1, all columns of the constraint matrix (A - I) are searched.

- Otherwise, A and I are partitioned to give i roughly equal segments A_j , I_j (j = 1 to i). If the previous pricing search was successful on A_j , I_j , the next search begins on the segments A_{j+1} , I_{j+1} . (All subscripts here are modulo i.)
- If a reduced gradient is found that is larger than some dynamic tolerance, the variable with the largest such reduced gradient (of appropriate sign) is selected to become superbasic. If nothing is found, the search continues on the next segments A_{j+2} , I_{j+2} , and so on.
- Partial price t (or t/2 or t/3) may be appropriate for time-stage models having t time periods.

Pivot tolerance r Default $=\epsilon^{2/3} pprox 3.7 \mathrm{e}$ -11

During solution of QP subproblems, the pivot tolerance is used to prevent columns entering the basis if they would cause the basis to become almost singular.

- When x changes to $x+\alpha p$ for some search direction p, a "ratio test" is used to determine which component of x reaches an upper or lower bound first. The corresponding element of p is called the pivot element.
- Elements of p are ignored (and therefore cannot be pivot elements) if they are smaller than the pivot tolerance r.
- It is common for two or more variables to reach a bound at essentially the same time. In such cases, the Minor Feasibility tolerance (say t) provides some freedom to maximize the pivot element and thereby improve numerical stability. Excessively small values of t should therefore not be specified.
- ullet To a lesser extent, the Expand frequency (say f) also provides some freedom to maximize the pivot element. Excessively *large* values of f should therefore not be specified.

Print file f Default = 15 Print frequency k Default = 100

If f > 0 and Minor print level > 0, a line of the QP iteration log will be printed on file f every kth minor iteration.

Proximal point method i Default = 1

i = 1 or 2 specifies minimization of $||x - x_0||_1$ or $\frac{1}{2}||x - x_0||_2^2$ when the starting point x_0 is changed to satisfy the linear constraints (where x_0 refers to nonlinear variables).

Punch file f Default = 0

If f > 0, the final solution obtained will be output to file f in the format described in Section 9.2. For linear programs, this format is compatible with various commercial systems.

QPSolver Cholesky

Default

QPSolver CG QPSolver QN

Specifies the active-set algorithm used to solve the QP subproblem. QPSolver Cholesky holds the full Cholesky factor R of the reduced Hessian Z^THZ . As the QP iterations proceed, the dimension of R changes with the number of superbasic variables. If it is necessary that the number of superbasic variables increases beyond the value of Reduced Hessian dimension, the reduced Hessian cannot be stored and the solver switches to QPSolver CG. The Cholesky solver is reactivated if the number of superbasics stabilizes at a value less than Reduced Hessian dimension.

QPSolver QN solves the QP subproblem using a quasi-Newton method similar to MINOS. In this case, R is the factor of a quasi-Newton approximate Hessian.

QPSolver CG uses an active-set method similar to QPSolver QN, but uses the conjugate-gradient method to solve all systems involving the reduced Hessian.

- The Cholesky QP solver is the most robust, but may require a significant amount of computation if the number of superbasics is large.
- The quasi-Newton QP solver does not require the computation of the R at the start of each QP and may be appropriate when the number of superbasics is large, but each QP subproblem requires relatively few minor iterations.
- The conjugate-gradient QP solver is appropriate for problems with large numbers of degrees of freedom.

Reduced Hessian dimension same as Hessian dimension

Default = $\min\{1000, n_1 + 1\}$

This specifies that an $r \times r$ triangular matrix R is to be available for use by the Cholesky QP solver (to define the reduced Hessian according to $R^T R = Z^T H Z$).

Save frequency

k

Default = 100

If a NEW BASIS file has been specified, a basis map describing the current solution will be saved on the appropriate file every kth iteration. A BACKUP BASIS file will also be saved if specified.

Scale option
Scale tolerance

i

Default = 2 (LP) or 1 (NLP)

Default = 0.9

Scale Print

Three scale options are available as follows:

- i Meaning
- 0 No scaling. This is recommended if it is known that x and the constraint matrix (and Jacobian) never have very large elements (say, larger than 1000).
- 1 Linear constraints and variables are scaled by an iterative procedure that attempts to make the matrix coefficients as close as possible to 1.0 (see Fourer [6]). This will sometimes improve the performance of the solution procedures.

All constraints and variables are scaled by the iterative procedure. Also, an additional scaling is performed that takes into account columns of $\begin{pmatrix} A & -I \end{pmatrix}$ that are fixed or have positive lower bounds or negative upper bounds.

If nonlinear constraints are present, the scales depend on the Jacobian at the first point that satisfies the linear constraints. Scale option 2 should therefore be used only if (a) a good starting point is provided, and (b) the problem is not highly nonlinear.

Scale tolerance affects how many passes might be needed through the constraint matrix. On each pass, the scaling procedure computes the ratio of the largest and smallest nonzero coefficients in each column:

$$\rho_j = \max_i |a_{ij}| / \min_i |a_{ij}| \qquad (a_{ij} \neq 0).$$

If $\max_j \rho_j$ is less than r times its previous value, another scaling pass is performed to adjust the row and column scales. Raising r from 0.9 to 0.99 (say) usually increases the number of scaling passes through A. At most 10 passes are made.

Scale Print causes the row-scales r(i) and column-scales c(j) to be printed. The scaled matrix coefficients are $\bar{a}_{ij} = a_{ij}c(j)/r(i)$, and the scaled bounds on the variables and slacks are $\bar{l}_j = l_j/c(j)$, $\bar{u}_j = u_j/c(j)$, where $c(j) \equiv r(j-n)$ if j > n.

The first four options determine whether the final solution obtained is to be output to the PRINT file. The file option operates independently; if f > 0, the final solution will be output to file f (whether optimal or not).

- For the first and third options, floating-point numbers are printed in f16.5 format, and "infinite" bounds are denoted by the word None.
- For the File option, all numbers are printed in 1p, e16.6 format, including "infinite" bounds, which will have magnitude 1.000000e+20.
- To see more significant digits in the printed solution, it is sometimes useful to make f refer to the PRINT file (i.e., make it the same as the number specified by Print file).

Start	Objective	Check	at Column	k	Default = 1
Start	Constraint	Check	at Column	k	Default = 1
Stop	Objective	Check	at Column	l	$Default = n'_1$
Stop	Constraint	Check	at Column	l	Default = n_1''

These keywords are not allowed in the snOptA interface. If Verify level > 0, they may be used to abbreviate the verification of individual derivative elements computed by subroutines funobj, funcon and usrfun. For example:

• If the first 100 objective gradients appeared to be correct in an earlier run, and if you have just found a bug in funobj that ought to fix up the 101-th component, then you might as well specify Start Objective Check at Column 101. Similarly for columns of the Jacobian.

• If the first 100 variables occur nonlinearly in the constraints, and the remaining variables are nonlinear only in the objective, then funobj must set the first 100 components of g(*) to zero, but these hardly need to be verified. The above option would again be appropriate.

Summary file f Default = 6 Summary frequency k Default = 100

If f > 0 and Minor print level > 0, a line of the QP iteration log will be output to file f every kth minor iteration.

Superbasics limit i Default $= n_1 + 1$

This places a limit on the storage allocated for superbasic variables. Ideally, i should be set slightly larger than the "number of degrees of freedom" expected at an optimal solution.

For linear programs, an optimum is normally a basic solution with no degrees of freedom. (The number of variables lying strictly between their bounds is no more than m, the number of general constraints.) The default value of i is therefore 1.

For nonlinear problems, the number of degrees of freedom is often called the "number of independent variables".

Normally, i need not be greater than n_1+1 , where n_1 is the number of nonlinear variables. For many problems, i may be considerably smaller than n_1 . This will save storage if n_1 is very large.

Suppress Parameters

Normally SNOPT prints the SPECS file as it is being read, and then prints a complete list of the available options and their final values. The Suppress Parameters option tells SNOPT not to print the full list.

Total	real	workspace	maxrw	Default = lenrw
Total	integer	workspace	maxiw	Default = leniw
Total	character	workspace	maxcw	Default = lencw
User	real	workspace	maxru	Default = 500
User	integer	workspace	maxiu	Default = 500
User	character	workspace	maxcu	Default = 500

These options may be used to confine SNOPT to certain parts of its workspace arrays cw, iw, rw. (The arrays are defined by the last six parameters of SNOPT.)

The Total ... options place an *upper* limit on SNOPT's workspace. They may be useful on machines with virtual memory. For example, some systems allow a very large array rw(lenrw) to be declared at compile time with no overhead in saving the resulting object code. At run time, when various problems of different size are to be solved, it may be sensible to restrict SNOPT to the lower end of rw in order to reduce paging activity slightly. (However, SNOPT accesses storage contiguously wherever possible, so the benefit may be slight. In general it is far better to have too much storage than not enough.)

If SNOPT's "user" parameters ru, lenru happen to be the same as rw, lenrw, the nonlinear function routines will be free to use ru(maxrw + 1: lenru) for their own purpose. Similarly for the other work arrays.

The User ... options place a *lower* limit on SNOPT's workspace (not counting the first 500 elements). Again, if SNOPT's parameters ru, lenru happen to be the same as

rw, lenrw, the function routines will be free to use ru(501: maxru) for their own purpose. Similarly for the other work arrays.

System Information No System Information Yes

Default

This option allows the knowledgeable user to print some additional information on the progress of the major and minor iterations.

Timing level i Default = 3

i=0 suppresses output of cpu times. (Intended for installations with dysfunctional timing routines.)

Unbounded objective value Unbounded step size

 f_{\max} α_{\max}

Default = 1.0e+15

Default = 1.0e+18

These parameters are intended to detect unboundedness in nonlinear problems. (They may not achieve that purpose!) During a line search, f_0 is evaluated at points of the form $x+\alpha p$, where x and p are fixed and α varies. if $|f_0|$ exceeds f_{\max} or α exceeds α_{\max} , iterations are terminated with the exit message Problem is unbounded (or badly scaled).

If singularities are present, unboundedness in $f_0(x)$ may be manifested by a floatingpoint overflow (during the evaluation of $f_0(x + \alpha p)$), before the test against f_{max} can be made

Unboundedness in x is best avoided by placing finite upper and lower bounds on the variables.

Verify level l Default = 0

This option refers to finite-difference checks on the derivatives computed by the user-provided routines. Derivatives are checked at the first point that satisfies all bounds and linear constraints.

- l Meaning
- Only a "cheap" test will be performed, requiring 2 calls to usrfun for snOptA, and 2 calls to funcon and 3 calls to funobj for snOptB.
- 1 Individual gradients will be checked (with a more reliable test). A key of the form "OK" or "Bad?" indicates whether or not each component appears to be correct.
- 2 Individual columns of the problem Jacobian will be checked.
- 3 Options 2 and 1 will both occur (in that order).
- -1 Derivative checking is disabled.

Verify level 3 should be specified whenever a new function routine is being developed. The Start and Stop keywords may be used to limit the number of nonlinear variables checked. Missing derivatives are not checked, so they result in no overhead.

Violation limit au Default = 10

This keyword defines an absolute limit on the magnitude of the maximum constraint violation after the line search. On completion of the line search, the new iterate x_{k+1} satisfies the condition

$$v_i(x_{k+1}) \le \tau \max\{1, v_i(x_0)\},\tag{7.3}$$

where x_0 is the point at which the nonlinear constraints are first evaluated and $v_i(x)$ is the *i*th nonlinear constraint violation $v_i(x) = \max(0, l_i - f_i(x), f_i(x) - u_i)$.

The effect of this violation limit is to restrict the iterates to lie in an expanded feasible region whose size depends on the magnitude of τ . This makes it possible to keep the iterates within a region where the objective is expected to be well-defined and bounded below. If the objective is bounded below for all values of the variables, then τ may be any large positive value.

8. Output

Subroutine snInit specifies unit numbers for the PRINT and SUMMARY files described in this section. The files can be redirected with the Print file and Summary file options (or suppressed).

8.1. The PRINT file

If Print file > 0, the following information is output to the PRINT file during the solution process. All printed lines are less than 131 characters.

- A listing of the SPECS file, if any.
- A listing of the options that were or could have been set in the SPECS file.
- An estimate of the working storage needed and the amount available.
- Some statistics about the problem being solved.
- The storage available for the *LU* factors of the basis matrix.
- A summary of the scaling procedure, if Scale option > 0.
- Notes about the initial basis resulting from a CRASH procedure or a BASIS file.
- The major iteration log.
- The minor iteration log.
- Basis factorization statistics.
- The EXIT condition and some statistics about the solution obtained.
- The printed solution, if requested.

The last five items are described in the following sections.

8.2. The major iteration log

If Major print level > 0, one line of information is output to the PRINT file every kth minor iteration, where k is the specified Print frequency (default k = 1).

Label Description

Itns The cumulative number of minor iterations.

Major The current major iteration number.

Minors is the number of iterations required by both the feasibility and optimality phases of the QP subproblem. Generally, Minors will be 1 in the later iterations, since theoretical analysis predicts that the correct active set will be identified near the solution (see Section 2).

Step The step length α taken along the current search direction p. The variables x have just been changed to $x + \alpha p$. On reasonably well-behaved problems, the unit step will be taken as the solution is approached.

nCon The number of times subroutines usrfun or funcon have been called to evaluate the nonlinear problem functions. Evaluations needed for the estimation of the derivatives by finite differences are not included. nCon is printed as a guide to the amount of work required for the line search.

Feasible is the value of rowerr, the maximum component of the scaled nonlinear constraint residual (7.1). The solution is regarded as acceptably feasible if Feasible is less than the Major feasibility tolerance. In this case, the entry is contained in parenthesis.

If the constraints are linear, all iterates are feasible and this entry is not printed.

Optimal is the value of maxgap, the maximum complementarity gap (7.2). It is an estimate of the degree of nonoptimality of the reduced costs. Both Feasbl and Optimal are small in the neighborhood of a solution.

MeritFunction is the value of the augmented Lagrangian merit function (see (2.2)). This function will decrease at each iteration unless it was necessary to increase the penalty parameters (see Section 2). As the solution is approached, Merit will converge to the value of the objective at the solution.

In elastic mode, the merit function is a composite function involving the constraint violations weighted by the elastic weight.

If the constraints are linear, this item is labeled Objective, the value of the objective function. It will decrease monotonically to its optimal value.

L+U The number of nonzeros representing the basis factors L and U on completion of the QP subproblem.

If nonlinear constraints are present, the basis factorization B = LU is computed at the start of the first minor iteration. At this stage, $\mathtt{LU} = \mathtt{lenL} + \mathtt{lenU}$, where \mathtt{lenL} , the number of subdiagonal elements in the columns of a lower triangular matrix and \mathtt{lenU} is the number of diagonal and superdiagonal elements in the rows of an upper-triangular matrix.

As columns of B are replaced during the minor iterations, LU may fluctuate up or down but in general will tend to increase. As the solution is approached and the minor iterations decrease towards zero, LU will reflect the number of nonzeros in the LU factors at the start of the QP subproblem.

If the constraints are linear, refactorization is subject only to the Factorize frequency, and LU will tend to increase between factorizations.

BSwap The number of columns of the basis matrix B that were swapped with columns of S to improve the condition of B. The swaps are determined by an LU factorization of the rectangular matrix $B_S = (B \ S)^T$ with stability being favored more than sparsity.

nS The current number of superbasic variables.

CondHz An estimate of the condition number of R^TR , an estimate of Z^THZ , the reduced Hessian of the Lagrangian. It is the square of the ratio of the largest and smallest diagonals of the upper triangular matrix R (which is a lower bound on the condition number of R^TR). Cond Hz gives a rough indication of whether or not the optimization procedure is having difficulty. If ϵ is the relative precision of the machine being used, the SQP algorithm will make slow progress if Cond Hz becomes as large as $\epsilon^{-1/2} \approx 10^8$, and will probably fail to find a better solution if Cond Hz reaches $\epsilon^{-3/4} \approx 10^{12}$.

To guard against high values of Cond Hz, attention should be given to the scaling of the variables and the constraints. In some cases it may be necessary to add upper or lower bounds to certain variables to keep them a reasonable distance from singularities in the nonlinear functions or their derivatives.

Penalty is the Euclidean norm of the vector of penalty parameters used in the augmented Lagrangian merit function (not printed if there are no nonlinear constraints).

The summary line may include additional code characters that indicate what happened during the course of the major iteration.

~

Code Meaning

- c Central differences have been used to compute the unknown components of the objective and constraint gradients. A switch to central differences is made if either the line search gives a small step, or x is close to being optimal. In some cases, it may be necessary to re-solve the QP subproblem with the central-difference gradient and Jacobian.
- d During the line search it was necessary to decrease the step in order to obtain a maximum constraint violation conforming to the value of Violation limit.
- The norm-wise change in the variables was limited by the value of the Major step limit. If this output occurs repeatedly during later iterations, it may be worthwhile increasing the value of Major step limit.
- i If SNOPT is not in elastic mode, an "i" signifies that the QP subproblem is infeasible. This event triggers the start of nonlinear elastic mode, which remains in effect for all subsequent iterations. Once in elastic mode, the QP subproblems are associated with the elastic problem $NP(\gamma)$.
 - If SNOPT is already in elastic mode, an "i" indicates that the minimizer of the elastic subproblem does not satisfy the linearized constraints. (In this case, a feasible point for the usual QP subproblem may or may not exist.)
- M An extra evaluation of the problem functions was needed to define an acceptable positive-definite quasi-Newton update to the Lagrangian Hessian. This modification is only done when there are nonlinear constraints.
- m This is the same as "M" except that it was also necessary to modify the update to include an augmented Lagrangian term.
- n No positive-definite BFGS update could be found. The approximate Hessian is unchanged from the previous iteration.
- R The approximate Hessian has been reset by discarding all but the diagonal elements. This reset will be forced periodically by the Hessian frequency and Hessian updates keywords. However, it may also be necessary to reset an ill-conditioned Hessian from time to time.
- r The approximate Hessian was reset after ten consecutive major iterations in which no BFGS update could be made. The diagonals of the approximate Hessian are retained if at least one update has been done since the last reset. Otherwise, the approximate Hessian is reset to the identity matrix.
- s A self-scaled BFGS update was performed. This update is used when the Hessian approximation is diagonal, and hence always follows a Hessian reset.
- t The minor iterations were terminated because of the Minor iterations limit.
- The minor iterations were terminated because of the New superbasics limit.
- u The QP subproblem was unbounded.
- w A weak solution of the QP subproblem was found.
- z The Superbasics limit was reached.

8.3. The minor iteration log

If Minor print level > 0, one line of information is output to the PRINT file every kth minor iteration, where k is the specified Minor print frequency (default k=1). A heading is printed before the first such line following a basis factorization. The heading contains the items described below. In this description, a PRICE operation is defined to be the process by which a nonbasic variable is selected to become superbasic (in addition to those already in the superbasic set). The selected variable is denoted by jq. Variable jq often becomes basic immediately. Otherwise it remains superbasic, unless it reaches its opposite bound and returns to the nonbasic set.

If Partial price is in effect, variable jq is selected from A_{pp} or I_{pp} , the ppth segments of the constraint matrix (A - I).

Label

Description

Itn The current iteration number.

RedCost,QPmult This is the reduced cost (or reduced gradient) of the variable jq selected by PRICE at the start of the present iteration. Algebraically, dj is $d_j = g_j - \pi^T a_j$ for j = jq, where g_j is the gradient of the current objective function, π is the vector of dual variables for the QP subproblem, and a_j is the jth column of (A - I).

Note that dj is the 1-norm of the reduced-gradient vector at the start of the iteration, just after the PRICE operation.

LPstep,QPstep The step length α taken along the current search direction p. The variables x have just been changed to $x + \alpha p$. If a variable is made superbasic during the current iteration (+SBS > 0), Step will be the step to the nearest bound. During Phase 2, the step can be greater than one only if the reduced Hessian is not positive definite.

nInf The number of infeasibilities *after* the present iteration. This number will not increase unless the iterations are in elastic mode.

SumInf If nInf > 0, this is sInf, the sum of infeasibilities after the present iteration. It usually decreases at each nonzero Step, but if nInf decreases by 2 or more, SumInf may occasionally increase.

In elastic mode, the heading is changed to Composite Obj, and the value printed decreases monotonically.

rgNorm The norm of the reduced-gradient vector at the start of the iteration. (It is the norm of the vector with elements d_j for variables j in the superbasic set.) During Phase 2 this norm will be approximately zero after a unit step.

(The heading is not printed if the problem is linear.)

LPobjective, QPobjective, Elastic QPobj The QP objective function after the present iteration. In elastic mode, the heading is changed to Elastic QPobj. In either case, the value printed decreases monotonically.

+SBS The variable jq selected by PRICE to be added to the superbasic set.

-SBS The superbasic variable chosen to become nonbasic.

-BS The variable removed from the basis (if any) to become nonbasic.

Pivot If column a_q replaces the rth column of the basis B, Pivot is the rth element of a vector y satisfying $By = a_q$. Wherever possible, Step is chosen to avoid extremely small values of Pivot (since they cause the basis to be nearly singular). In rare

cases, it may be necessary to increase the Pivot tolerance to exclude very small elements of y from consideration during the computation of Step.

L+U The number of nonzeros representing the basis factors L and U. Immediately after a basis factorization B = LU, this is lenL+lenU, the number of subdiagonal elements in the columns of a lower triangular matrix and the number of diagonal and superdiagonal elements in the rows of an upper-triangular matrix. Further nonzeros are added to L when various columns of B are later replaced. As columns of B are replaced, the matrix U is maintained explicitly (in sparse form). The value of L will steadily increase, whereas the value of U may fluctuate up or down. Thus, in general, the value of L+U may fluctuate up or down; in general it will tend to increase.)

The number of compressions required to recover storage in the data structure for U. This includes the number of compressions needed during the previous basis factorization. Normally ncp should increase very slowly. If not, the amount of integer and real workspace available to SNOPT should be increased by a significant amount. As a suggestion, the work arrays iw(*) and rw(*) should be extended by L + U elements.

nS The current number of superbasic variables. (The heading is not printed if the problem is linear.)

cond Hz See the major iteration log. (The heading is not printed if the problem is linear.)

8.4. Basis factorization statistics

If Major print level ≥ 10 , the following items are output to the PRINT file whenever the basis B or the rectangular matrix $B_S = (B \ S)^T$ is factorized before solution of the next QP subproblem.

Note that B_S may be factorized at the start of just some of the major iterations. It is immediately followed by a factorization of B itself.

Gaussian elimination is used to compute a sparse LU factorization of B or B_S , where PLP^T and PUQ are lower and upper triangular matrices for some permutation matrices P and Q. Stability is ensured as described under LU factor tolerance in Section 7.6.

If Minor print level ≥ 10 , the same items are printed during the QP solution whenever the current B is factorized.

Label

Description

Factorize The number of factorizations since the start of the run.

Demand A code giving the reason for the present factorization.

Code Meaning

- 0 First LU factorization.
- 1 The number of updates reached the Factorization Frequency.
- 2 The nonzeros in the updated factors have increased significantly.
- 7 Not enough storage to update factors.
- 10 Row residuals too large (see the description of Check Frequency).
- 11 Ill-conditioning has caused inconsistent results.

Itn The current minor iteration number.

Nonlin The number of nonlinear variables in the current basis B.

Linear The number of linear variables in B.

Slacks The number of slack variables in B.

B BR BS or BT factorize The type of LU factorization.

B Periodic factorization of the basis B.

BR More careful rank-revealing factorization of B using threshold rook pivoting. This occurs mainly at the start, if the first basis factors seem singular or ill-conditioned. Followed by a normal B factorize.

BS B_S is factorized to choose a well-conditioned B from the current $(B \ S)$. Followed by a normal B factorize.

Same as BS except the current B is tried first and accepted if it appears to be not much more ill-conditioned than after the previous BS factorize.

m The number of rows in B or B_s .

n The number of columns in B or B_s . Preceded by "=" or ">" respectively.

Elems The number of nonzero elements in B or B_s .

Amax The largest nonzero in B or B_s .

Density The percentage nonzero density of B or B_s .

Merit The average Markowitz merit count for the elements chosen to be the diagonals of PUQ. Each merit count is defined to be (c-1)(r-1) where c and r are the number of nonzeros in the column and row containing the element at the time it is selected to be the next diagonal. Merit is the average of \mathbf{n} such quantities. It gives an indication of how much work was required to preserve sparsity during the factorization.

lenL The number of nonzeros in L.

Cmpressns The number of times the data structure holding the partially factored matrix needed to be compressed to recover unused storage. Ideally this number should be zero. If it is more than 3 or 4, the amount of workspace available to SNOPT should be increased for efficiency.

Incres The percentage increase in the number of nonzeros in L and U relative to the number of nonzeros in B or B_s .

Utri is the number of triangular rows of B or B_s at the top of U.

lenU The number of nonzeros in U.

Ltol The maximum subdiagonal element allowed in L. This is the specified LU factor tolerance or a smaller value that is currently being used for greater stability.

Umax The maximum nonzero element in U.

Ugrwth The ratio Umax/Amax, which ideally should not be substantially larger than 10.0 or 100.0. If it is orders of magnitude larger, it may be advisable to reduce the LU factor tolerance to 5.0, 4.0, 3.0 or 2.0, say (but bigger than 1.0).

As long as Lmax is not large (say 10.0 or less), $\max\{\text{Amax}, \text{Umax}\}\/$ DUmin gives an estimate of the condition number of B. If this is extremely large, the basis is nearly singular. Slacks are used to replace suspect columns of B and the modified basis is refactored.

Ltri is the number of triangular columns of B or B_S at the left of L.

dense1 is the number of columns remaining when the density of the basis matrix being

factorized reached 0.3.

Lmax The actual maximum subdiagonal element in L (bounded by Ltol).

Akmax The largest nonzero generated at any stage of the LU factorization. (Values

much larger than Amax indicate instability.)

growth The ratio Akmax/Amax. Values much larger than 100 (say) indicate instability.

bump is the size of the "bump" or block to be factorized nontrivially after the trian-

gular rows and columns of B or B_s have been removed.

dense2 is the number of columns remaining when the density of the basis matrix being

factorized reached 0.6. (The Markowitz pivot strategy searches fewer columns

at that stage.)

DUmax The largest diagonal of PUQ.

DUmin The smallest diagonal of PUQ.

condU The ratio DUmax/DUmin, which estimates the condition number of U (and of B

if Ltol is less than 100, say).

8.5. Crash statistics

If Major print level ≥ 10 , the following items are output to the PRINT file when Start = 'Cold' and no basis file is loaded. They refer to the number of columns that the CRASH procedure selects during several passes through A while searching for a triangular basis matrix.

Label Description

Slacks is the number of slacks selected initially.

Free cols is the number of free columns in the basis, including those whose bounds are rather far apart.

Preferred is the number of "preferred" columns in the basis (i.e., hs(j) = 3 for some $j \le n$). It will be a subset of the columns for which hs(j) = 3 was specified.

Unit is the number of unit columns in the basis.

Double is the number of columns in the basis containing 2 nonzeros.

Triangle is the number of triangular columns in the basis with 3 or more nonzeros.

Pad is the number of slacks used to pad the basis (to make it a nonsingular triangle).

8.6. EXIT conditions

When any solver or auxililiary routine in the SNOPT package terminates, a message is printed that summarizes what happened during the run. The general form of the output message is:

SOLVER EXIT e -- exit condition

SOLVER INFO i -- informational message

where e is an integer that labels the particular $exit\ condition$, and i is one of several alternative $informational\ messages$ that elaborate on the exit condition. For example, solver snOptA may print the message:

SNOPTA EXIT 20 -- the problem appears to be unbounded SNOPTA INFO 21 -- unbounded objective

Note that in this example, the exit condition gives a broad definition of what happened, while the informational message is more specific about the cause of the termination.

The number i associated with the informational message is the output value of the argument INFO. Note that the number e associated with the exit condition may always be recovered from INFO by stripping off the least significant decimal digit.

The list of possible exit conditions are:

- 0 Finished successfully
- 10 The problem appears to be infeasible
- 20 The problem appears to be unbounded
- 30 Resource limit error
- 40 Terminated after numerical difficulties
- 50 Error in the user-supplied functions
- 60 Undefined user-supplied functions
- 70 User requested termination
- 80 Insufficient storage allocated
- 90 Input arguments out of range
- 100 Finished successfully (associated with SNOPT auxiliary routines)
- 110 Errors while processing MPS data
- 120 Errors while estimating Jacobian structure
- 130 Errors while reading OPTIONS file
- 140 System error

The exit conditions 0–20 arise when a solution exists (though it may not be optimal). A BASIS file may be saved, and the solution will be output to the PRINT or SOLUTION files if requested.

Here we describe each message and suggest possible courses of action.

```
EXIT -- 0 Finished successfully
INFO -- 1 optimality conditions satisfied
INFO -- 2 feasible point found (from option Feasible point only)
INFO -- 3 requested accuracy could not be achieved
```

This message should be the cause of guarded optimism! It is certainly preferable to every other message, and we naturally want to believe what it says.

In all cases, a distinct level of caution is in order. For example, if the objective value is much better than expected, we may have obtained an optimal solution to the wrong problem! Almost any item of data could have that effect if it has the wrong value. Verifying that the problem has been defined correctly is one of the more difficult tasks for a model builder. It is good practice in the function subroutines to print any data that is input during the first entry.

If nonlinearities exist, one must always ask the question: could there be more than one local optimum? When the constraints are linear and the objective is known to be convex (e.g., a sum of squares) then all will be well if we are *minimizing* the objective: a local minimum is a global minimum in the sense that no other point has a lower function value. (However, many points could have the *same* objective value, particularly if the objective is largely linear.) Conversely, if we are *maximizing* a convex function, a local maximum cannot be expected to be global, unless there are sufficient constraints to confine the feasible region.

Similar statements could be made about nonlinear constraints defining convex or concave regions. However, the functions of a problem are more likely to be neither convex nor concave. Our advice is always to specify a starting point that is as good an estimate as possible, and to include reasonable upper and lower bounds on all variables, in order to confine the solution to the specific region of interest. We expect modelers to know something about their problem, and to make use of that knowledge as they themselves know best.

One other caution about "Optimality conditions satisfied". Some of the variables or slacks may lie outside their bounds more than desired, especially if scaling was requested. Some information concerning the run can be obtained from the short summary given at the end of the print and summary files. Here is an example from the problem Toy discussed in Section 3.2.

```
SNOPTA EXIT 0 -- finished successfully SNOPTA INFO 1 -- optimality conditions satisfied
```

Problem name	Toy1		
No. of iterations	7	Objective value	-1.0000000008E+00
No. of major iterations	7	Linear objective	0.000000000E+00
Penalty parameter	3.253E-02	Nonlinear objective	-1.000000008E+00
No. of calls to funobj	9	No. of calls to fun	con 9
No. of degenerate steps	0	Percentage	0.00
Max x	2 1.0E+00	Max pi	1 1.2E-01
Max Primal infeas	0 0.0E+00	Max Dual infeas	2 8.0E-10
Nonlinear constraint violn	6.4E-09		

Max Primal infeas refers to the largest bound infeasibility and which variable is involved. If it is too large, consider restarting with a smaller Minor feasibility tolerance (say 10 times smaller) and perhaps Scale option 0.

Similarly, Max Dual infeas indicates which variable is most likely to be at a non-optimal value. Broadly speaking, if

```
Max Dual infeas/Max pi = 10^{-d},
```

then the objective function would probably change in the dth significant digit if optimization could be continued. If d seems too large, consider restarting with a smaller Major optimality tolerance.

Finally, Nonlinear constraint violn shows the maximum infeasibility for nonlinear rows. If it seems too large, consider restarting with a smaller Major feasibility tolerance.

If the requested accuracy could not be achieved, a feasible solution has been found, but the requested accuracy in the dual infeasibilities could not be achieved. An abnormal termination has occurred, but SNOPT is within 10^{-2} of satisfying the Major optimality tolerance. Check that the Major optimality tolerance is not too small.

```
EXIT -- 10 The problem appears to be infeasible
```

INFO -- 11 infeasible linear constraints

INFO -- 12 infeasible linear equalities

INFO -- 13 nonlinear infeasibilities minimized

INFO -- 14 infeasibilities minimized

This exit occurs if SNOPT is unable to find a point that satisfies the constraints.

When the constraints are *linear*, the output messages are based on a relatively reliable indicator of infeasibility. Feasibility is measured with respect to the upper and lower bounds on the variables and slacks. Among all the points satisfying the general constraints Ax - s = 0, there is apparently no point that satisfies the bounds on x and s. Violations as small as the Minor feasibility tolerance are ignored, but at least one component of x or s violates a bound by more than the tolerance.

When nonlinear constraints are present, infeasibility is much harder to recognize correctly. Even if a feasible solution exists, the current linearization of the constraints may not contain a feasible point. In an attempt to deal with this situation, when solving each QP subproblem, SNOPT is prepared to relax the bounds on the slacks associated with nonlinear rows.

If a QP subproblem proves to be infeasible or unbounded (or if the Lagrange multiplier estimates for the nonlinear constraints become large), SNOPT enters so-called "nonlinear elastic" mode. The subproblem includes the original QP objective and the sum of the infeasibilities—suitably weighted using the Elastic weight parameter. In elastic mode, some of the bounds on the nonlinear rows "elastic"—i.e., they are allowed to violate their specified bounds. Variables subject to elastic bounds are known as elastic variables. An elastic variable is free to violate one or both of its original upper or lower bounds. If the original problem has a feasible solution and the elastic weight is sufficiently large, a feasible point eventually will be obtained for the perturbed constraints, and optimization can continue on the subproblem. If the nonlinear problem has no feasible solution, SNOPT will tend to determine a "good" infeasible point if the elastic weight is sufficiently large. (If the elastic weight were infinite, SNOPT would locally minimize the nonlinear constraint violations subject to the linear constraints and bounds.)

Unfortunately, even though SNOPT locally minimizes the nonlinear constraint violations, there may still exist other regions in which the nonlinear constraints are satisfied. Wherever possible, nonlinear constraints should be defined in such a way that feasible points are known to exist when the constraints are linearized.

```
EXIT -- 20 The problem appears to be unbounded
```

For linear problems, unboundedness is detected by the simplex method when a nonbasic variable can be increased or decreased by an arbitrary amount without causing a basic

INFO -- 21 unbounded objective

INFO -- 22 constraint violation limit reached

variable to violate a bound. A message prior to the EXIT message will give the index of the nonbasic variable. Consider adding an upper or lower bound to the variable. Also, examine the constraints that have nonzeros in the associated column, to see if they have been formulated as intended.

Very rarely, the scaling of the problem could be so poor that numerical error will give an erroneous indication of unboundedness. Consider using the Scale option.

For nonlinear problems, SNOPT monitors both the size of the current objective function and the size of the change in the variables at each step. If either of these is very large (as judged by the Unbounded parameters—see Section 7.6), the problem is terminated and declared unbounded. To avoid large function values, it may be necessary to impose bounds on some of the variables in order to keep them away from singularities in the nonlinear functions.

The second informational message indicates an abnormal termination while enforcing the limit on the constraint violations. This exit implies that the objective is not bounded below in the feasible region defined by expanding the bounds by the value of the Violation limit.

```
EXIT -- 30 Resource limit error
```

INFO -- 31 iteration limit reached

INFO -- 32 major iteration limit reached

INFO -- 33 the superbasics limit is too small

Either the Iterations limit or the Major iterations limit was exceeded before the required solution could be found. Check the iteration log to be sure that progress was being made. If so, restart the run using a basis file that was saved (or should have been saved!) at the end of the run.

If the superbasics limit is too small, then the problem appears to be more nonlinear than anticipated. The current set of basic and superbasic variables have been optimized as much as possible and a PRICE operation is necessary to continue, but there are already Superbasics limit superbasics (and no room for any more).

```
EXIT -- 40 Terminated after numerical difficulties
```

INFO -- 41 current point cannot be improved

INFO -- 42 singular basis

INFO -- 43 cannot satisfy the general constraints

INFO -- 44 ill-conditioned null-space basis

Several circumstances may lead to SNOPT not being able to improve on a non-optimal point.

- Subroutines usrfun, funobj or funcon could be returning accurate function values but inaccurate gradients (or vice versa). This is the most likely cause. Study the comments given for INFO 51 and 52, and do your best to ensure that the coding is correct.
- 2. The function and gradient values could be consistent, but their precision could be too low. For example, accidental use of a real data type when double precision was intended would lead to a relative function precision of about 10^{-6} instead of something like 10^{-15} . The default Major optimality tolerance of 10^{-6} would need to be raised to about 10^{-3} for optimality to be declared (at a rather suboptimal point). Of course, it is better to revise the function coding to obtain as much precision as economically possible.
- 3. If function values are obtained from an expensive iterative process, they may be accurate to rather few significant figures, and gradients will probably not be available.

One should specify

Function precision t Major optimality tolerance \sqrt{t}

but even then, if t is as large as 10^{-5} or 10^{-6} (only 5 or 6 significant figures), the same exit condition may occur. At present the only remedy is to increase the accuracy of the function calculation.

Termination because of a singular basis is highly unlikely to occur. The first factorization attempt will have found the basis to be structurally or numerically singular. (Some diagonals of the triangular matrix U were respectively zero or smaller than a certain tolerance.) The associated variables are replaced by slacks and the modified basis is refactorized, but singularity persists. This must mean that the problem is badly scaled, or the LU factor tolerance is too much larger than 1.0.

If the general constraints cannot be satisfied, an LU factorization of the basis has just been obtained and used to recompute the basic variables x_B , given the present values of the superbasic and nonbasic variables. A step of "iterative refinement" has also been applied to increase the accuracy of x_B . However, a row check has revealed that the resulting solution does not satisfy the current constraints Ax - s = 0 sufficiently well.

This probably means that the current basis is very ill-conditioned. If there are some linear constraints and variables, try Scale option 1 if scaling has not yet been used.

For certain highly structured basis matrices (notably those with band structure), a systematic growth may occur in the factor U. Consult the description of Umax, Umin and Growth in Section 8.4, and set the LU factor tolerance to 2.0 (or possibly even smaller, but not less than 1.0).

EXIT -- 50 Error in the user-supplied functions

INFO -- 51 incorrect objective derivatives

INFO -- 52 incorrect constraint derivatives

This exit implies that there may be errors in the subroutines that define the problem objective and constraints. If the objective derivatives appear to incorrect, a check has been made on some individual elements of the objective gradient array at the first point that satisfies the linear constraints. At least one component (G(k)) or gObj(j) is being set to a value that disagrees markedly with its associated forward-difference estimate $\partial f_0/\partial x_j$. (The relative difference between the computed and estimated values is 1.0 or more.) This exit is a safeguard, since SNOPT will usually fail to make progress when the computed gradients are seriously inaccurate. In the process it may expend considerable effort before terminating with INFO 41 above.

Check the function and gradient computation very carefully in usrfun or funobj. A simple omission (such as forgetting to divide f_0 by 2) could explain everything. If f_0 or a component $\partial f_0/\partial x_j$ is very large, then give serious thought to scaling the function or the nonlinear variables.

If you feel certain that the computed gObj(j) is correct (and that the forward-difference estimate is therefore wrong), you can specify Verify level O to prevent individual elements from being checked. However, the optimization procedure may have difficulty.

If some constraint derivatives appear to be incorrect, then at least one of the computed constraint derivatives is significantly different from an estimate obtained by forward-differencing the vector F(x). Follow the advice given above for the objective function, trying to ensure that the arrays F and G are being set correctly in usrfun or funcon.

```
EXIT -- 60 Undefined user-supplied functions

INFO -- 61 undefined function at the first feasible point

INFO -- 62 undefined function at the initial point

INFO -- 63 unable to proceed into undefined region
```

If the user assigns the value $\mathtt{Status} = -1$ in any of the routines \mathtt{usrfun} , \mathtt{funobj} or \mathtt{funcon} computing the problem functions, then the function is considered to be "undefined" at that point. SNOPT attempts to evaluate the problem functions closer to a point at which the functions have already been computed. INFO 61 and 62 indicate that SNOPT is unable to proceed because the functions are undefined at the initial point or first feasible point. INFO 63 implies that repeated attempts to move into a region where the functions are not defined resulted in the change in variables being unacceptably small.

```
EXIT -- 70 User requested termination
INFO -- 71 terminated during function evaluation
INFO -- 72 terminated during constraint evaluation
INFO -- 73 terminated during objective evaluation
INFO -- 74 terminated from monitor routine
```

These exits occur when Status < -1 is set during some call to the user-defined routines. SNOPT assumes that you want the problem to be abandoned forthwith.

If the following exits occur during the *first* basis factorization, the primal and dual variables **x** and **pi** will have their original input values. BASIS files will be saved if requested, but certain values in the printed solution will not be meaningful.

```
EXIT -- 80 Insufficient storage allocated
INFO -- 81 work arrays must have at least 500 elements
INFO -- 82 not enough character storage
INFO -- 83 not enough integer storage
INFO -- 84 not enough real storage
```

EXIT -- 90 Input arguments out of range

SNOPT cannot start to solve a problem unless the char, int and real work arrays are at least 500 elements.

If the main character, integer or real storage arrays cw(*), iw(*) and rw(*) are not large enough for the current problem, the routine declaring cw(*), iw and rw should be recompiled with a larger dimensions for those arrays. The new values should also be assigned to lencw, leniw and lenrw. An estimate of the additional storage required is given in messages preceding the exit.

If rw(*) is not large enough, be sure that the Hessian dimension is not unreasonably large.

```
INFO -- 91 invalid input argument
INFO -- 92 basis file dimensions do not match this problem
This exit occurs if some data associated with the problem is out of range. If INFO = 91, at least one input argument for the interface is invalid. The printed output provides more detail about which argument(s) must be modified.
```

If INFO = 92 an OLD BASIS file could not be loaded properly. (In this situation, New BASIS files cannot be saved, and there is no solution to print.) On the first line of the OLD BASIS file, the dimensions labeled m and n are different from those associated with the

problem that has just been defined. You have probably loaded a file that belongs to another problem.

Remember, if you are using snOptA and you have added elements to A(*), iAfun(*), and jAvar(*) or iGfun(*), and jGvar(*), you will have to alter m and n and the map beginning on the third line (a hazardous operation). It may be easier to restart with a PUNCH or DUMP file from an earlier version of the problem.

The basis file state vector will not match the current problem if, for some reason, the OLD BASIS file is incompatible with the present problem, or is not consistent within itself. The number of basic entries in the state vector (i.e., the number of 3's in the map) is not the same as \mathbf{m} on the first line, or some of the 2's in the map did not have a corresponding " $j \ x_j$ " entry following the map.

```
EXIT -- 140 System error
INFO -- 141 wrong number of basic variables
INFO -- 142 error in basis package
```

These messages arise if either an OLD BASIS file could not be loaded properly, or some fatal system error has occurred. New BASIS files cannot be saved, and there is no solution to print. The problem is abandoned.

An inconsistency in the number of basic variables should never happen. It may indicate that the wrong SNOPT source files have been compiled, or incorrect parameters have been used in the call to one of the SNOPT interfaces.

Check that all integer variables and arrays are declared integer in your calling program, and that all "real" variables and arrays are declared consistently. (They should be double precision on most machines.)

If there is an error in basis package, a preceding message will describe the error in more detail. One such message says that the current basis has more than one element in row i and column j. This could be caused by a corresponding error in the input parameters, i.e., the arrays A(*), iAfun(*), jAvar(*), iGfun(*), and jGvar(*) for snOptA, or indA, Acol and locA for snOptB.

8.7. Solution output

At the end of a run, the final solution is output to the PRINT file in accordance with the Solution keyword. Some header information appears first to identify the problem and the final state of the optimization procedure. A ROWS section and a COLUMNS section then follow, giving one line of information for each row and column. The format used is similar to certain commercial systems, though there is no industry standard.

An example of the printed solution is given in Section 8. In general, numerical values are output with format f16.5. The maximum record length is 111 characters, including the first (carriage-control) character.

To reduce clutter, a dot "." is printed for any numerical value that is exactly zero. The values ± 1 are also printed specially as 1.0 and -1.0. Infinite bounds ($\pm 10^{20}$ or larger) are printed as None.

Note: If two problems are the same except that one minimizes an objective $f_0(x)$ and the other maximizes $-f_0(x)$, their solutions will be the same but the signs of the dual variables π_i and the reduced gradients d_j will be reversed.

The ROWS section

General linear constraints take the form $l \leq Ax \leq u$. The *i*th constraint is therefore of the form

$$\alpha \le a^T x \le \beta,$$

and the value of a^Tx is called the *row activity*. Internally, the linear constraints take the form Ax - s = 0, where the slack variables s should satisfy the bounds $l \le s \le u$. For the ith "row", it is the slack variable s_i that is directly available, and it is sometimes convenient to refer to its state. Slacks may be basic or nonbasic (but not superbasic).

Nonlinear constraints $\alpha \leq f_i(x) + a^T x \leq \beta$ are treated similarly, except that the row activity and degree of infeasibility are computed directly from $f_i(x) + a^T x$ rather than s_i .

Label Description

Number The value n + i. This is the internal number used to refer to the *i*th slack in the iteration log.

Row The name of the ith row.

State The state of the *i*th row relative to the bounds α and β . The various states possible are as follows.

- LL The row is at its lower limit, α .
- UL The row is at its upper limit, β .
- EQ The limits are the same $(\alpha = \beta)$.
- BS The constraint is not binding. s_i is basic.

A key is sometimes printed before the State to give some additional information about the state of the slack variable.

- A Alternative optimum possible. The slack is nonbasic, but its reduced gradient is essentially zero. This means that if the slack were allowed to start moving from its current value, there would be no change in the objective function. The values of the basic and superbasic variables might change, giving a genuine alternative solution. The values of the dual variables might also change.
- D Degenerate. The slack is basic, but it is equal to (or very close to) one of its bounds.
- I Infeasible. The slack is basic and is currently violating one of its bounds by more than the Feasibility tolerance.
- Not precisely optimal. The slack is nonbasic. Its reduced gradient is larger than the Major optimality tolerance .

Note: If Scale option > 0, the tests for assigning A, D, I, N are made on the scaled problem because the keys are then more likely to be meaningful.

Activity The row value a^Tx (or $f_i(x) + a^Tx$ for nonlinear rows).

Slack activity The amount by which the row differs from its nearest bound. (For free rows, it is taken to be minus the Activity.)

Lower limit α , the lower bound on the row.

Upper limit β , the upper bound on the row.

- Dual activity The value of the dual variable π_i , often called the shadow price (or simplex multiplier) for the *i*th constraint. The full vector π always satisfies $B^T\pi = g_B$, where B is the current basis matrix and g_B contains the associated gradients for the current objective function.
- I The constraint number, i.

The COLUMNS section

Here we talk about the "column variables" x_j , j = 1: n. We assume that a typical variable has bounds $\alpha \leq x_j \leq \beta$.

Label

Description

Number The column number, j. This is the internal number used to refer to x_j in the iteration log.

Column The name of x_i .

State The state of x_j relative to the bounds α and β . The various states possible are as follows.

LL x_j is nonbasic at its lower limit, α .

UL x_j is nonbasic at its upper limit, β .

EQ x_j is nonbasic and fixed at the value $\alpha = \beta$.

FR x_j is nonbasic at some value strictly between its bounds: $\alpha < x_j < \beta$.

BS x_j is basic. Usually $\alpha < x_j < \beta$.

SBS x_j is superbasic. Usually $\alpha < x_j < \beta$.

A key is sometimes printed before the State to give some additional information about the state of x_i .

- A Alternative optimum possible. The variable is nonbasic, but its reduced gradient is essentially zero. This means that if x_j were allowed to start moving from its current value, there would be no change in the objective function. The values of the basic and superbasic variables might change, giving a genuine alternative solution. The values of the dual variables might also change.
- D Degenerate. x_i is basic, but it is equal to (or very close to) one of its bounds.
- I Infeasible. x_j is basic and is currently violating one of its bounds by more than the Feasibility tolerance.
- Not precisely optimal. x_j is nonbasic. Its reduced gradient is larger than the Major optimality tolerance.

Note: If Scale option > 0, the tests for assigning A, D, I, N are made on the scaled problem because the keys are then more likely to be meaningful.

Activity The value of the variable x_j .

Obj Gradient g_j , the jth component of the gradient of the (linear or nonlinear) objective function. (If any x_j is infeasible, g_j is the gradient of the sum of infeasibilities.)

Lower limit α , the lower bound on x_i .

Upper limit β , the upper bound on x_i .

Reduced gradnt The reduced gradient $d_j = g_j - \pi^T a_j$, where a_j is the jth column of the constraint matrix (or the jth column of the Jacobian at the start of the final major iteration).

M+J The value m+j.

8.8. The SOLUTION file

The information in a printed solution (Section 8.7) may be output as a SOLUTION file, according to the Solution file option (which may refer to the PRINT file if so desired). Infinite bounds appear as $\pm 10^{20}$ rather than None. Other numerical values are output with format 1p, e16.6.

A SOLUTION file is intended to be read from disk by a self-contained program that extracts and saves certain values as required for possible further computation. Typically the first 14 records would be ignored. Each subsequent record may be read using

adapted to suit the occasion. The end of the ROWS section is marked by a record that starts with a 1 and is otherwise blank. If this and the next 4 records are skipped, the COLUMNS section can then be read under the same format. (There should be no need for backspace statements.)

8.9. The SUMMARY file

If Summary file > 0, the following information is output to the SUMMARY file. (It is a brief form of the PRINT file.) All output lines are less than 72 characters.

- The Begin line from the SPECS file, if any.
- The basis file loaded, if any.
- A brief Major iteration log.
- A brief Minor iteration log.
- The EXIT condition and a summary of the final solution.

The following SUMMARY file is from the example of Section 3.2, using Major print level 1 and Minor print level 0.

9. Basis Files

For non-trivial problems, it is advisable to save a BASIS file at the end of a run, in order to restart the run if necessary, or to provide a good starting point for some closely related problem.

Three formats are available for saving basis descriptions. They are invoked by SPECS lines of the following form:

New Basis	file	10
Backup	file	11
Punch	file	20
Dump	file	30

The file numbers may be whatever is convenient, or zero for files that are not wanted.

NEW BASIS and BACKUP BASIS files are saved in that order every kth iteration, where k is the Save frequency.

NEW BASIS, PUNCH and DUMP files are saved at the end of a run, in that order. They may be re-loaded at the start of a subsequent run by specifying SPECS lines of the following form:

Old Basis	file	10
Insert	file	20
Load	file	30

Only one such file will actually be loaded. If more than one positive file number is specified, the order of precedence is as shown. If no BASIS files are specified, one of the Crash options takes effect.

Figures 3–5 illustrate the data formats used for BASIS files. 80-character fixed-length records are suitable in all cases. (36-character records would be adequate for PUNCH and DUMP files.) The files shown correspond to the optimal solution for the economic-growth model MANNE. (The problem has 10 nonlinear constraints, 10 linear constraints, and 30 variables.) Selected column numbers are included to define significant data fields.

9.1. NEW and OLD BASIS files

We sometimes call these files *basis maps*. They contain the most compact representation of the state of each variable. They are intended for restarting the solution of a problem at a point that was reached by an earlier run on the *same problem* or a related problem with the *same dimensions*. (Perhaps the Iterations limit was previously too small, or some other objective row is to be used.)

As illustrated in Figure 3, the following information is recorded in a NEW BASIS file.

- 1. A line containing the problem name, the iteration number when the file was created, the status of the solution (Optimal Soln, Infeasible, Unbounded, Excess Itns, Error Condn, or Proceeding), the number of infeasibilities, and the current objective value (or the sum of infeasibilities).
- 2. A line containing the OBJECTIVE, RHS, RANGES and BOUNDS names, M = m, the number of rows in the constraint matrix, N = n, the number of columns in the constraint matrix, and SB = the number of superbasic variables.
- 3. A set of (n+m-1)/80+1 lines indicating the state of the n column variables and the m slack variables in that order. One character hs(j) is recorded for each j=1:n+m as follows, written with format(80i1).

hs(j) State of the jth variable

- O Nonbasic at lower bound
- 1 Nonbasic at upper bound
- 2 Superbasic
- 3 Basic

If variable j is nonbasic, it may be fixed (lower bound = upper bound), or free (infinite bounds), or it may be strictly between its bounds. In such cases, hs(j) = 0. (Free variables will almost always be basic.)

4. A set of lines of the form

$$j$$
 x_i

written with format(i8, 1p, e24.14) and terminated by an entry with j = 0, where j denotes the jth variable and x_j is a real value. The jth variable is either the jth column or the (j-n)th slack, if j > n. Typically, hs(j) = 2 (superbasic). When nonlinear constraints are present, this list of superbasic variables is extended to include all basic nonlinear variables. The Jacobian matrix can then be reconstructed exactly for a restart. The list also includes nonbasic variables that lie strictly between their bounds.

Loading a NEW BASIS file

A file that has been saved as an OLD BASIS file may be input at the beginning of a later run as a NEW BASIS file. The following notes are relevant:

- 1. The first line is input and printed but otherwise not used.
- 2. The values labeled M and N on the second line must agree with m and n for the problem that has just been defined. The value labeled SB is input and printed but is not used.
- 3. The next set of lines must contain exactly m values hs(j) = 3, denoting the basic variables.
- 4. The list of j and x_j values must include an entry for every variable whose state is hs(j) = 2 (the superbasic variables).
- 5. Further j and x_i values may be included, in any order.
- 6. For any j in this list, if hs(j) = 3 (basic), the value x_j will be recorded for nonlinear variables, but the variable will remain basic.
- 7. If $hs(j) \neq 3$, variable j will be initialized at the value x_j and its state will be reset to 2 (superbasic). If the number of superbasic variables has already reached the Superbasics limit, then variable j will be made nonbasic at its current value (even if it is not equal to one of its bounds).

Figure 3: Format of NEW and OLD BASIS files

9.2. PUNCH and INSERT files

These files provide compatibility with commercial mathematical programming systems. The PUNCH file from a previous run may be used as an INSERT file for a later run on the same problem. It may also be possible to modify the INSERT file and/or problem and still obtain a useful advanced basis.

The standard MPS format has been slightly generalized to allow the saving and reloading of nonbasic solutions. It is illustrated in Figure 4. Apart from the first and last line, each entry has the following form:

Columns 2-3 5-12 15-22 25-36 Contents Key Name1 Name2 Value

The various keys are best defined in terms of the action they cause on input. It is assumed that the basis is initially set to be the full set of slack variables, and that column variables are initially at their smallest bound in absolute magnitude, or zero for free variables.

Key Action to be taken during INSERT

- XL Make variable Name1 basic and slack Name2 nonbasic at its lower bound.
- XU Make variable Name1 basic and slack Name2 nonbasic at its upper bound.
- LL Make variable *Name1* nonbasic at its lower bound.
- UL Make variable *Name1* nonbasic at its upper bound.
- SB Make variable Name1 superbasic at the specified Value.

Note that Name1 may be a column name or a row name, but on XL and XU lines, Name2 must be a row name. In all cases, row names indicate the associated slack variable, and if Name1 is a nonlinear variable then its Value is recorded for possible use in defining the initial Jacobian matrix.

The key SB is an addition to the standard MPS format to allow for nonbasic solutions.

Notes on PUNCH data

- 1. Variables are output in natural order. For example, on the first XL or XU line, Name1 will be the first basic column and Name2 will be the first row whose slack is not basic.
- 2. LL lines are *not* output for nonbasic variables if the corresponding lower bound value is zero.

Notes on INSERT data

- 1. Before an INSERT file is read, column variables are made nonbasic at their smallest bound in absolute magnitude, and the slack variables are made basic.
- 2. Preferably an INSERT file should be an unmodified PUNCH file from an earlier run on the same problem. If some rows have been added to the problem, the INSERT file need not be altered. (The slacks for the new rows will be in the basis.)
- 3. Entries will be ignored if *Name1* is already basic or superbasic. XL and XU lines will be ignored if *Name2* is not basic.
- 4. SB lines may be added before the ENDATA line, to specify additional superbasic columns or slacks.
- 5. An SB line will not alter the status of *Name1* if the Superbasics limit has been reached. However, the associated *Value* will be retained.

9.3. DUMP and LOAD files

These files are similar to PUNCH and INSERT files, but they record solution information in a manner that is more direct and more easily modified. In particular, no distinction is made between columns and slacks. Apart from the first and last line, each entry has the form

Columns 2-3 5-12 25-36Contents Key Name Value

as illustrated in Figure 5. The keys LL, UL, BS and SB mean Lower Limit, Upper Limit, Basic and Superbasic respectively.

Notes on DUMP data

- 1. A line is output for every variable, columns followed by slacks.
- 2. Nonbasic variables between their bounds will be output with key LL and their current value.

Notes on LOAD data

- 1. Before a LOAD file is read, all columns and slacks are made nonbasic at their smallest bound in absolute magnitude. The basis is initially empty.
- 2. BS causes Name to become basic.
- 3. SB causes Name to become superbasic at the specified Value.
- 4. LL or UL cause Name to be nonbasic at the specified Value.
- 5. An entry will be ignored if *Name* is already basic or superbasic. (Thus, only the first BS or SB line takes effect for any given *Name*.)
- 6. An SB line will not alter the status of *Name* if the Superbasics limit has been reached, but the associated *Value* will be retained if *Name* is a Jacobian variable.
- 7. (Partial basis) Let m be the number of rows in the problem. If fewer than m variables are specified to be basic, a tentative basis list will be constructed by adding the requisite number of slacks, starting from the first row and taking those that were not previously specified to be basic or superbasic. (If the resulting basis proves to be singular, the basis factorization routine will replace a number of basic variables by other slacks.)
- 8. (*Too many basics*) If m variables have already been specified as basic, any further BS keys will be treated as though they were SB. This feature may be useful for combining solutions to smaller problems.
