# NAG Fortran Library Routine Document D05BDF

Note: before using this routine, please read the Users' Note for your implementation to check the interpretation of **bold italicised** terms and other implementation-dependent details.

## 1 Purpose

D05BDF computes the solution of a weakly singular nonlinear convolution Volterra–Abel integral equation of the second kind using a fractional Backward Differentiation Formulae (BDF) method.

# 2 Specification

```
SUBROUTINE DO5BDF(CK, CF, CG, INITWT, IORDER, TLIM, TOLNL, NMESH, YN,

WORK, LWK, NCT, IFAIL)

INTEGER

IORDER, NMESH, LWK, NCT(NMESH/32+1), IFAIL

CK, CF, CG, TLIM, TOLNL, YN(NMESH), WORK(LWK)

CHARACTER*1

EXTERNAL

CK, CF, CG
```

# 3 Description

D05BDF computes the numerical solution of the weakly singular convolution Volterra-Abel integral equation of the second kind

$$y(t) = f(t) + \frac{1}{\sqrt{\pi}} \int_0^t \frac{k(t-s)}{\sqrt{t-s}} g(s, y(s)) \, ds, \ 0 \le t \le T.$$
 (1)

Note the constant  $\frac{1}{\sqrt{\pi}}$  in (1). It is assumed that the functions involved in (1) are sufficiently smooth.

The routine uses a fractional BDF linear multi-step method selected by the user to generate a family of quadrature rules (see D05BYF). The BDF methods available in D05BDF are of orders 4, 5 and 6 (= p say). For a description of theoretical and practical background related to these methods we refer to Lubich (1985), to Baker and Derakhshan (1987) and Hairer *et al.* (1988) respectively.

The algorithm is based on computing the solution y(t) in a step-by-step fashion on a mesh of equispaced points. The size of the mesh is given by T/(N-1), N being the number of points at which the solution is sought. These methods require 2p-1 (including y(0)) starting values which are evaluated internally. The computation of the lag term arising from the discretization of (1) is performed by fast Fourier transform (FFT) techniques when N > 32 + 2p - 1, and directly otherwise. The routine does not provide an error estimate and users are advised to check the behaviour of the solution with a different value of N. An option is provided which avoids the re-evaluation of the fractional weights when D05BDF is to be called several times (with the same value of N) within the same program unit with different functions.

## 5 Parameters

1: CK - real FUNCTION, supplied by the user.

External Procedure

CK must evaluate the kernel k(t) of the integral equation (1).

Its specification is:

real FUNCTION CK(T)
real T

1: T - real
On entry: the value of the independent variable, t.

CK must be declared as EXTERNAL in the (sub)program from which D05BDF is called. Parameters denoted as *Input* must **not** be changed by this procedure.

2: CF - real FUNCTION, supplied by the user.

External Procedure

CF must evaluate the function f(t) in (1).

Its specification is:

real FUNCTION CF(T)
real T

1: T - real
On entry: the value of the independent variable, t.

CF must be declared as EXTERNAL in the (sub)program from which D05BDF is called. Parameters denoted as *Input* must **not** be changed by this procedure.

3: CG – *real* FUNCTION, supplied by the user.

External Procedure

CG must evaluate the function g(s, y(s)) in (1).

Its specification is:

real FUNCTION CG(S, Y)
real S, Y

1: S - real Input
On entry: the value of the independent variable, s.

2: Y - real Input

CG must be declared as EXTERNAL in the (sub)program from which D05BDF is called. Parameters denoted as *Input* must **not** be changed by this procedure.

On entry: the value of the solution y at the point s.

## 4: INITWT – CHARACTER\*1

Input

On entry: if the fractional weights required by the method need to be calculated by the routine, then set INITWT = 'I' (Initial call).

If INITWT = 'S' (Subsequent call), then the routine assumes the fractional weights have been computed on a previous call and are stored in WORK.

Constraint: INITWT = 'I' or 'S'.

D05BDF.2 [NP3546/20A]

**Note:** when D05BDF is re-entered with the value of INITWT = 'S', the values of NMESH, IORDER and the contents of WORK **must** not be changed.

#### 5: IORDER – INTEGER

Input

On entry: the order of the BDF method to be used, p.

Constraint:  $4 \leq IORDER \leq 6$ .

Suggested value: IORDER = 4.

6: TLIM - real

Input

On entry: the final point of the integration interval, T.

Constraint: TLIM  $> 10 \times$  machine precision.

7: TOLNL - real

Input

On entry: the accuracy required for the computation of the starting value and the solution of the nonlinear equation at each step of the computation (see Section 8).

Constraint: TOLNL >  $10 \times$  machine precision.

Suggested value: TOLNL =  $\sqrt{\epsilon}$  where  $\epsilon$  is the machine precision.

#### 8: NMESH – INTEGER

Input

On entry: the number of equispaced points, N, at which the solution is sought.

Constraint: NMESH =  $2^m + 2 \times IORDER - 1$ , where  $m \ge 1$ .

#### 9: YN(NMESH) – *real* array

Output

On exit: YN(i) contains the approximate value of the true solution y(t) at the point  $t = (i - 1) \times h$ , for i = 1,2,...,NMESH, where h = TLIM/(NMESH - 1).

## 10: WORK(LWK) – *real* array

Workspace

11: LWK - INTEGER

Input

On entry: the dimension of the array WORK as declared in the (sub)program from which D05BDF is called.

Constraint: LWK  $\geq (2 \times IORDER + 6) \times NMESH + 8 \times IORDER^2 - 16 \times IORDER + 1$ .

12: NCT(NMESH/32+1) – INTEGER array

Workspace

#### 13: IFAIL – INTEGER

Input/Output

On entry: IFAIL must be set to 0, -1 or 1. Users who are unfamiliar with this parameter should refer to Chapter P01 for details.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

For environments where it might be inappropriate to halt program execution when an error is detected, the value -1 or 1 is recommended. If the output of error messages is undesirable, then the value 1 is recommended. Otherwise, for users not familiar with this parameter the recommended value is 0. When the value -1 or 1 is used it is essential to test the value of IFAIL on exit.

# 6 Error Indicators and Warnings

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

Errors or warnings detected by the routine:

IFAIL = 1

```
On entry, IORDER < 4 or IORDER > 6, or TLIM \leq 10 \times machine precision, or INITWT \neq 'I' or 'S', or INITWT = 'S' on the first call to D05BDF, or TOLNL \leq 10 \times machine precision, or NMESH \neq 2^m + 2 \times IORDER -1, m \geq 1, or LWK < (2 \times IORDER +6) \times NMESH +8 \times IORDER<sup>2</sup> -16 \times IORDER +1.
```

IFAIL = 2

The routine cannot compute the 2p-1 starting values due to an error solving the system of nonlinear equations. Relaxing the value of TOLNL and/or increasing the value of NMESH may overcome this problem (see Section 8 for further details).

IFAIL = 3

The routine cannot compute the solution at a specific step due to an error in the solution of single nonlinear equation (2). Relaxing the value of TOLNL and/or increasing the value of NMESH may overcome this problem (see Section 8 for further details).

## 7 Accuracy

The accuracy depends on NMESH and TOLNL, the theoretical behaviour of the solution of the integral equation and the interval of integration. The value of TOLNL controls the accuracy required for computing the starting values and the solution of (2) at each step of computation. This value can affect the accuracy of the solution. However, for most problems, the value of  $\sqrt{\epsilon}$ , where  $\epsilon$  is the *machine precision*, should be sufficient.

In general, for the choice of BDF method, the user is recommended to use the fourth-order BDF formula (i.e., IORDER = 4).

#### **8** Further Comments

In solving (1), initially, D05BDF computes the solution of a system of nonlinear equations for obtaining the 2p-1 starting values. C05NDF is used for this purpose. When a failure with IFAIL = 2 occurs (which corresponds to an error exit from C05NDF), users are advised to either relax the value of TOLNL or choose a smaller step size by increasing the value of NMESH. Once the starting values are computed successfully, the solution of a nonlinear equation of the form

$$Y_n - \alpha g(t_n, Y_n) - \Psi_n = 0, \tag{2}$$

is required at each step of computation, where  $\Psi_n$  and  $\alpha$  are constants. D05BDF calls C05AXF to find the root of this equation.

If a failure with IFAIL = 3 occurs (which corresponds to an error exit from C05AXF), users are advised to relax the value of the TOLNL or choose a smaller step size by increasing the value of NMESH.

If a failure with IFAIL = 2 or 3 persists even after adjustments to TOLNL and/or NMESH then the user should consider whether there is a more fundamental difficulty. For example, the problem is ill-posed or the functions in (1) are not sufficiently smooth.

## 9 Example

We solve the following integral equations

$$y(t) = \sqrt{t} + \frac{3}{8}\pi t^2 - \int_0^t \frac{1}{\sqrt{t-s}} [y(s)]^3 ds, \ 0 \le t \le 7,$$

with the solution  $y(t) = \sqrt{t}$ , and

D05BDF.4 [NP3546/20A]

$$y(t) = (3-t)\sqrt{t} - \int_0^t \frac{1}{\sqrt{t-s}} \exp(s(1-s)^2 - [y(s)]^2) ds, \ 0 \le t \le 5,$$

with the solution  $y(t) = (1 - t)\sqrt{t}$ . In the above examples, the fourth-order BDF is used, and NMESH is set to  $2^6 + 7$ .

## 9.1 Program Text

**Note:** the listing of the example program presented below uses **bold italicised** terms to denote precision-dependent details. Please read the Users' Note for your implementation to check the interpretation of these terms. As explained in the Essential Introduction to this manual, the results produced may not be identical for all implementations.
