NAG Fortran Library Routine Document F02FDF

Note: before using this routine, please read the Users' Note for your implementation to check the interpretation of **bold italicised** terms and other implementation-dependent details.

1 Purpose

F02FDF computes all the eigenvalues, and optionally all the eigenvectors, of a real symmetric-definite generalized eigenproblem.

2 Specification

```
SUBROUTINE F02FDF(ITYPE, JOB, UPLO, N, A, LDA, B, LDB, W, WORK, LWORK,

IFAIL)

INTEGER ITYPE, N, LDA, LDB, LWORK, IFAIL

real A(LDA,*), B(LDB,*), W(*), WORK(LWORK)

CHARACTER*1 JOB, UPLO
```

3 Description

This routine computes all the eigenvalues, and optionally all the eigenvectors, of a real symmetric-definite generalized eigenproblem of one of the following types:

- 1. $Az = \lambda Bz$
- 2. $ABz = \lambda z$
- 3. $BAz = \lambda z$

Here A and B are symmetric, and B must be positive-definite.

The method involves implicitly inverting B; hence if B is ill-conditioned with respect to inversion, the results may be inaccurate (see Section 7).

Note that the matrix Z of eigenvectors is not orthogonal, but satisfies the following relationships for the three types of problem above:

- 1. $Z^TBZ = I$
- 2. $Z^TBZ = I$
- 3. $Z^T B^{-1} Z = I$

5 Parameters

1: ITYPE – INTEGER Input

On entry: indicates the type of problem, as follows:

if ITYPE = 1, the problem is $Az = \lambda Bz$;

if ITYPE = 2, the problem is $ABz = \lambda z$;

if ITYPE = 3, the problem is $BAz = \lambda z$.

Constraint: ITYPE = 1, 2 or 3.

2: JOB – CHARACTER*1

Input

On entry: indicates whether eigenvectors are to be computed as follows:

if JOB = 'N', then only eigenvalues are computed;

if JOB = 'V', then eigenvalues and eigenvectors are computed.

Constraint: JOB = 'N' or 'V'.

3: UPLO - CHARACTER*1

Input

On entry: indicates whether the upper or lower triangular parts of A and B are stored as follows:

if UPLO = 'U', then the upper triangular parts of A and B are stored;

if UPLO = 'L', then the lower triangular parts of A and B are stored.

Constraint: UPLO = 'U' or 'L'.

4: N – INTEGER

Input

On entry: n, the order of the matrices A and B.

Constraint: N > 0.

5: A(LDA,*) - real array

Input/Output

Note: the second dimension of the array A must be at least max(1, N).

On entry: the n by n symmetric matrix A. If UPLO = 'U', the upper triangle of A must be stored and the elements of the array below the diagonal need not be set; if UPLO = 'L', the lower triangle of A must be stored and the elements of the array above the diagonal need not be set.

On exit: If JOB = 'V', A contains the matrix Z of eigenvectors, with the ith column holding the eigenvector z_i associated with the eigenvalue λ_i (stored in W(i)). If JOB = 'N', the original contents of A are overwritten.

6: LDA – INTEGER

Input

On entry: the first dimension of the array A as declared in the (sub)program from which F02FDF is called.

Constraint: LDA $> \max(1, N)$.

7: B(LDB,*) - real array

Input/Output

Note: the second dimension of the array B must be at least max(1, N).

On entry: the n by n symmetric positive-definite matrix B. If UPLO = 'U', the upper triangle of B must be stored and the elements of the array below the diagonal are not referenced; if UPLO = 'L', the lower triangle of B must be stored and the elements of the array above the diagonal are not referenced.

On exit: the upper or lower triangle of B (as specified by UPLO) is overwritten by the triangular factor U or L from the Cholesky factorization of B as U^TU or LL^T .

F02FDF.2 [NP3546/20A]

8: LDB – INTEGER

Input

On entry: the first dimension of the array B as declared in the (sub)program from which F02FDF is called.

Constraint: LDB $\geq \max(1, N)$.

9: W(*) - real array

Output

Note: the dimension of the array W must be at least max(1, N).

On exit: the eigenvalues in ascending order.

10: WORK(LWORK) - *real* array

Workspace

11: LWORK – INTEGER

Input

On entry: the dimension of the array WORK as declared in the (sub)program from which F02FDF is called. On some high-performance computers, increasing the dimension of WORK will enable the routine to run faster; a value of $64 \times N$ should allow near-optimal performance on almost all machines.

Constraint: LWORK $\geq \max(1, 3 \times N)$.

12: IFAIL – INTEGER

Input/Output

On entry: IFAIL must be set to 0, -1 or 1. Users who are unfamiliar with this parameter should refer to Chapter P01 for details.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

For environments where it might be inappropriate to halt program execution when an error is detected, the value -1 or 1 is recommended. If the output of error messages is undesirable, then the value 1 is recommended. Otherwise, for users not familiar with this parameter the recommended value is 0. When the value -1 or 1 is used it is essential to test the value of IFAIL on exit.

6 Error Indicators and Warnings

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

Errors or warnings detected by the routine:

IFAIL = 1

```
On entry, ITYPE \neq 1, 2 \text{ or } 3, or JOB \neq 'N' \text{ or 'V'}, or UPLO \neq 'U' \text{ or 'L'}, or N < 0, or LDA < max(1, N), or LDB < max(1, N), or LWORK < max(1, 3 \times N).
```

IFAIL = 2

The QR algorithm failed to compute all the eigenvalues.

IFAIL = 3

The matrix B is not positive-definite.

[NP3546/20A] F02FDF.3

7 Accuracy

If λ_i is an exact eigenvalue, and $\tilde{\lambda_i}$ is the corresponding computed value, then

for problems of the form $Az = \lambda Bz$,

$$|\tilde{\lambda}_i - \lambda_i| \le c(n)\epsilon ||A||_2 ||B^{-1}||_2;$$

for problems of the form $ABz = \lambda z$ or $BAz = \lambda z$,

$$|\tilde{\lambda}_i - \lambda_i| \le c(n)\epsilon ||A||_2 ||B||_2$$
.

Here c(n) is a modestly increasing function of n, and ϵ is the **machine precision**.

If z_i is the corresponding exact eigenvector, and \tilde{z}_i is the corresponding computed eigenvector, then the angle $\theta(\tilde{z}_i, z_i)$ between them is bounded as follows:

for problems of the form $Az = \lambda Bz$,

$$\theta(\tilde{z}_i, z_i) \le \frac{c(n)\epsilon ||A||_2 ||B^{-1}||_2 (\kappa_2(B))^{1/2}}{\min_{i \ne j} |\lambda_i - \lambda_{j|}};$$

and for problems of the form $ABz = \lambda z$ or $BAz = \lambda z$,

$$\theta(\tilde{z}_i, z_i) \le \frac{c(n)\epsilon ||A||_2 ||B||_2 (\kappa_2(B))^{1/2}}{\min_{i \ne j} |\lambda_i - \lambda_j|}.$$

Here $\kappa_2(B)$ is the condition number of B with respect to inversion defined by: $\kappa_2(B) = \|B\| \cdot \|B^{-1}\|$. Thus the accuracy of a computed eigenvector depends on the gap between its eigenvalue and all the other eigenvalues, and also on the condition of B.

8 Further Comments

The routine calls routines from LAPACK in Chapter F08. It first reduces the problem to an equivalent standard eigenproblem $Cy=\lambda y$. It then reduces C to tridiagonal form T, using an orthogonal similarity transformation: $C=QTQ^T$. To compute eigenvalues only, the routine uses a root-free variant of the symmetric tridiagonal QR algorithm to reduce T to a diagonal matrix Λ . If eigenvectors are required, the routine first forms the orthogonal matrix Q that was used in the reduction to tridiagonal form; it then uses the symmetric tridiagonal QR algorithm to reduce T to Λ , using a further orthogonal transformation: $T=S\Lambda S^T$; and at the same time accumulates the matrix Y=QS, which is the matrix of eigenvectors of C. Finally it transforms the eigenvectors of C back to those of the original generalized problem.

Each eigenvector z is normalized so that:

for problems of the form $Az = \lambda Bz$ or $ABz = \lambda z$, $z^TBz = 1$;

for problems of the form $BAz = \lambda z$, $z^T B^{-1}z = 1$.

The time taken by the routine is approximately proportional to n^3 .

9 Example

To compute all the eigenvalues and eigenvectors of the problem $Az = \lambda Bz$, where

$$A = \begin{pmatrix} 0.24 & 0.39 & 0.42 & -0.16 \\ 0.39 & -0.11 & 0.79 & 0.63 \\ 0.42 & 0.79 & -0.25 & 0.48 \\ -0.16 & 0.63 & 0.48 & -0.03 \end{pmatrix} \text{ and } B = \begin{pmatrix} 4.16 & -3.12 & 0.56 & -0.10 \\ -3.12 & 5.03 & -0.83 & 1.18 \\ 0.56 & -0.83 & 0.76 & 0.34 \\ -0.10 & 1.18 & 0.34 & 1.18 \end{pmatrix}.$$
