NAG Fortran Library Routine Document F07APF (ZGESVX)

Note: before using this routine, please read the Users' Note for your implementation to check the interpretation of **bold italicised** terms and other implementation-dependent details.

1 Purpose

F07APF (ZGESVX) uses the LU factorization to compute the solution to a complex system of linear equations

$$AX = B$$
 or $A^TX = B$ or $A^HX = B$

where A is an n by n matrix and X and B are n by r matrices. Error bounds on the solution and a condition estimate are also provided.

2 Specification

```
SUBROUTINE FO7APF (FACT, TRANS, N, NRHS, A, LDA, AF, LDAF, IPIV, EQUED,
R, C, B, LDB, X, LDX, RCOND, FERR, BERR, WORK, RWORK,
INFO)

INTEGER
N, NRHS, LDA, LDAF, IPIV(*), LDB, LDX, INFO

double precision
R(*), C(*), RCOND, FERR(*), BERR(*), RWORK(*)

complex*16
CHARACTER*1
FACT, TRANS, EQUED
```

The routine may be called by its LAPACK name zgesvx.

3 Description

The following steps are performed:

1. If FACT = 'E', real scaling factors are computed to equilibrate the system:

if TRANS = 'N',
$$(D_R A D_C) (D_C^{-1}) = D_R B$$
;
if TRANS = 'T', $(D_R A D_C)^T (D_R^{-1} X) = D_C B$;
if TRANS = 'C', $(D_R A D_C)^H (D_R^{-1} X) = D_C B$;

where D_R and D_C are diagonal matrices with positive diagonal elements.

Whether or not the system will be equilibrated depends on the scaling of the matrix A, but if equilibration is used, A is overwritten by D_RAD_C and B by D_RB (if TRANS = 'N') or D_CB (if TRANS = 'T' or 'C').

2. If FACT = 'N' or 'E', the LU decomposition is used to factor the matrix A (after equilibration if FACT = 'E') as

$$A = PLU$$
.

where P is a permutation matrix, L is a unit lower triangular matrix, and U is upper triangular.

- 3. If some $u_{ii} = 0$, so that U is exactly singular, then the routine returns with INFO = i. Otherwise, the factorized form of A is used to estimate the condition number of the matrix A. If the reciprocal of the condition number is less than **machine precision**, INFO = N + 1 is returned as a warning, but the routine still goes on to solve for X and compute error bounds as described below.
- 4. The system of equations is solved for X using the factorized form of A.

[NP3657/21] F07APF (ZGESVX).1

- 5. Iterative refinement is applied to improve the computed solution matrix and to calculate error bounds and backward error estimates for the computed solution.
- 6. If equilibration was used, the matrix X is premultiplied by D_C (if TRANS = 'N') or D_R (if TRANS = 'T' or 'C') so that it solves the original system before equilibration.

5 Parameters

1: FACT – CHARACTER*1

Input

On entry: specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored:

if FACT = 'F' on entry, AF and IPIV contain the factored form of A. If EQUED \neq 'N', the matrix A has been equilibrated with scaling factors given by R and C. A, AF and IPIV are not modified;

if FACT = 'N', the matrix A will be copied to AF and factored;

if FACT = 'E', the matrix A will be equilibrated if necessary, then copied to AF and factored.

Constraint: FACT = 'F', 'N' or 'E'.

2: TRANS - CHARACTER*1

Input

On entry: specifies the form of the system of equations:

```
if TRANS = 'N', AX = B (No transpose);
if TRANS = 'T', A^TX = B (Transpose);
if TRANS = 'C', A^HX = B (Conjugate transpose).
```

Constraint: TRANS = 'N', 'T' or 'C'.

3: N – INTEGER

Input

On entry: n, the number of linear equations, i.e., the order of the matrix A.

Constraint: N > 0.

4: NRHS – INTEGER

Input

On entry: r, the number of right-hand sides, i.e., the number of columns of the matrix B.

Constraint: NRHS ≥ 0 .

5: A(LDA,*) - complex*16 array

Input/Output

Note: the second dimension of the array A must be at least max(1, N).

On entry: the n by n matrix A.

If FACT = 'F' and EQUED \neq 'N', A must have been equilibrated by the scaling factors in R and/or C.

F07APF (ZGESVX).2 [NP3657/21]

On exit: if EQUED \neq 'N', A is scaled as follows:

```
if EQUED = 'R', A = D_R A;
if EQUED = 'C', A = AD_C;
if EQUED = 'B', A = D_R AD_C.
```

A is not modified if FACT = 'F' or 'N', or if FACT = 'E' and EQUED = 'N' on exit.

6: LDA – INTEGER

On entry: the first dimension of the array A as declared in the (sub)program from which F07APF (ZGESVX) is called.

Constraint: LDA \geq max(1, N).

7: AF(LDAF,*) - complex*16 array

Input/Output

Input

Note: the second dimension of the array AF must be at least max(1, N).

On entry: if FACT = 'F', AF contains the factors L and U from the factorization A = PLU as computed by F07ARF (ZGETRF).

If EQUED \neq 'N', AF is the factored form of the equilibrated matrix A.

If FACT = 'N' or 'E', AF need not be set.

On exit: if FACT = 'N', AF returns the factors L and U from the factorization A = PLU of the original matrix A.

If FACT = 'E', AF returns the factors L and U from the factorization A = PLU of the equilibrated matrix A (see the description of A for the form of the equilibrated matrix).

If FACT = 'F', AF is unchanged from entry.

8: LDAF – INTEGER Input

On entry: the first dimension of the array AF as declared in the (sub)program from which F07APF (ZGESVX) is called.

Constraint: LDAF $\geq \max(1, N)$.

9: IPIV(*) - INTEGER array

Input/Output

Note: the dimension of the array IPIV must be at least max(1, N).

On entry: if FACT = 'F', IPIV contains the pivot indices from the factorization A = PLU as computed by F07ARF (ZGETRF); at the *i*th step row *i* of the matrix was interchanged with row IPIV(*i*).

If FACT = 'N' or 'E', IPIV need not be set. IPIV(i) = i indicates a row interchange was not required.

On exit: if FACT = 'N', IPIV contains the pivot indices from the factorization A = PLU of the original matrix A.

If FACT = 'E', IPIV contains the pivot indices from the factorization A = PLU of the equilibrated matrix A.

If FACT = 'E', IPIV is unchanged from entry.

10: EQUED - CHARACTER*1

Input/Output

On entry: if FACT = 'N' or 'E', EQUED need not be set.

If FACT = 'F', EQUED must specify the form of the equilibration that was performed as follows:

if EQUED = 'N', no equilibration;

if EQUED = 'R', row equilibration, i.e., A has been premultiplied by D_R ;

if EQUED = 'C', column equilibration, i.e., A has been postmultiplied by D_C ;

if EQUED = 'B', both row and column equilibration, i.e., A has been replaced by D_RAD_C .

[NP3657/21]

On exit: if FACT = 'F', EQUED is unchanged from entry.

Otherwise, if INFO \geq 0, EQUED specifies the form of equilibration that was performed as specified above.

Constraint: if FACT = 'F', EQUED = 'N', 'R', 'C' or 'B'.

11: R(*) – *double precision* array

Input/Output

Note: the dimension of the array R must be at least max(1, N).

On entry: if FACT = 'N' or 'E', R need not be set.

If FACT = 'F' and EQUED = 'R' or 'B', R must contain the row scale factors for A, D_R ; each element of R must be positive.

On exit: if FACT = 'F', R is unchanged from entry.

Otherwise, if INFO ≥ 0 and EQUED = 'R' or 'B', R contains the row scale factors for A, D_R , such that A is multiplied on the left by D_R ; each element of R is positive.

12: C(*) – *double precision* array

Input/Output

Note: the dimension of the array C must be at least max(1, N).

On entry: if FACT = 'N' or 'E', C need not be set.

If FACT = 'F' or EQUED = 'C' or 'B', C must contain the column scale factors for A, D_C ; each element of C must be positive.

On exit: if FACT = 'F', C is unchanged from entry.

Otherwise, if INFO ≥ 0 and EQUED = 'C' or 'B', C contains the row scale factors for A, D_C ; each element of C is positive.

13: B(LDB,*) - complex*16 array

Input/Output

Note: the second dimension of the array B must be at least max(1, NRHS).

On entry: the n by r right-hand side matrix B.

On exit: if EQUED = 'N', B is not modified.

If TRANS = 'N' and EQUED = 'R' or 'B', B is overwritten by D_RB .

If TRANS = 'T' or 'C' and EQUED = 'C' or 'B', B is overwritten by D_CB .

14: LDB – INTEGER

Input

On entry: the first dimension of the array B as declared in the (sub)program from which F07APF (ZGESVX) is called.

Constraint: LDB $\geq \max(1, N)$.

15: X(LDX,*) - complex*16 array

Output

Note: the second dimension of the array X must be at least max(1, NRHS).

On exit: if INFO = 0 or INFO = N + 1, the n by r solution matrix X to the original system of equations. Note that the arrays A and B are modified on exit if EQUED \neq 'N', and the solution to the equilibrated system is $D_C^{-1}X$ if TRANS = 'N' and EQUED = 'C' or 'B', or $D_R^{-1}X$ if TRANS = 'T' or 'C' and EQUED = 'R' or 'B'.

16: LDX – INTEGER

Input

On entry: the first dimension of the array X as declared in the (sub)program from which F07APF (ZGESVX) is called.

Constraint: $LDX \ge max(1, N)$.

F07APF (ZGESVX).4

17: RCOND – double precision

Output

On exit: if INFO ≥ 0 , an estimate of the reciprocal condition number of the matrix A (after equilibration if that is performed), computed as $\text{RCOND} = 1/(\|A\|_1 \|A^{-1}\|_1)$.

18: FERR(*) – *double precision* array

Output

Note: the dimension of the array FERR must be at least max(1, NRHS).

On exit: if INFO = 0 or INFO = N + 1, an estimate of the forward error bound for each computed solution vector, such that $\|\hat{x}_j - x_j\|_{\infty} / \|x_j\|_{\infty} \le \text{FERR}(j)$ where \hat{x}_j is the *j*th column of the computed solution returned in the array X and x_j is the corresponding column of the exact solution X. The estimate is as reliable as the estimate for RCOND, and is almost always a slight overestimate of the true error.

19: BERR(*) – *double precision* array

Output

Note: the dimension of the array BERR must be at least max(1, NRHS).

On exit: if INFO = 0 or INFO = N + 1, an estimate of the componentwise relative backward error of each computed solution vector \hat{x}_j (i.e., the smallest relative change in any element of A or B that makes \hat{x}_j an exact solution).

20: WORK(*) - complex*16 array

Workspace

Note: the dimension of the array WORK must be at least $max(1, 2 \times N)$.

21: RWORK(*) – *double precision* array

Output

Note: the dimension of the array RWORK must be at least $max(1, 2 \times N)$.

On exit: RWORK(1) contains the reciprocal pivot growth factor $\|A\|/\|U\|$. The 'max absolute element' norm is used. If RWORK(1) is much less than 1, then the stability of the LU factorization of the (equilibrated) matrix A could be poor. This also means that the solution X, condition estimator RCOND, and forward error bound FERR could be unreliable. If factorization fails with $0 < \text{INFO} \le N$, then RWORK(1) contains the reciprocal pivot growth factor for the leading INFO columns of A.

22: INFO – INTEGER

Output

On exit: INFO = 0 unless the routine detects an error (see Section 6).

6 Error Indicators and Warnings

Errors or warnings detected by the routine:

INFO < 0

If INFO = -i, the *i*th argument had an illegal value. An explanatory message is output, and execution of the program is terminated.

INFO = N + 1

U is nonsingular, but RCOND is less than *machine precision*, so that the matrix A is numerically singular. A solution to the equations AX = B, and corresponding error bounds, have nevertheless been computed because there are some situations where the computed solution can be more accurate that the value of RCOND would suggest.

INFO > 0 and INFO $\le N$

If INFO = i, u_{ii} is exactly zero. The factorization has been completed, but the factor U is exactly singular, so the solution and error bounds could not be computed. RCOND = 0 is returned.

[NP3657/21] F07APF (ZGESVX).5

U is nonsingular, but RCOND is less than *machine precision*, meaning that the matrix is singular to working precision. Nevertheless, the solution and error bounds are computed because there are a number of situations where the computed solution can be more accurate than the value of RCOND would suggest.

7 Accuracy

For each right-hand side vector b, the computed solution \hat{x} is the exact solution of a perturbed system of equations $(A+E)\hat{x}=b$, where

$$|E| \leq c(n)\epsilon P|L||U|,$$

c(n) is a modest linear function of n, and ϵ is the **machine precision**. See Section 9.3 of Higham (2002) for further details.

If x is the true solution, then the computed solution \hat{x} satisfies a forward error bound of the form

$$\frac{\|x - \hat{x}\|_{\infty}}{\|\hat{x}\|_{\infty}} \le w_c \operatorname{cond}(A, \hat{x}, b)$$

where $\operatorname{cond}(A,\hat{x},b) = \| |A^{-1}| (|A||\hat{x}| + |b|) \|_{\infty} / \|\hat{x}\|_{\infty} \leq \operatorname{cond}(A) = \| |A^{-1}| |A| \|_{\infty} \leq \kappa_{\infty}(A)$. If \hat{x} is the jth column of X, then w_c is returned in $\operatorname{BERR}(j)$ and a bound on $\|x - \hat{x}\|_{\infty} / \|\hat{x}\|_{\infty}$ is returned in $\operatorname{FERR}(j)$. See Section 4.4 of Anderson $et\ al.$ (1999) for further details.

8 Further Comments

The factorization of A requires approximately $\frac{8}{3}n^3$ floating point operations.

Estimating the forward error involves solving a number of systems of linear equations of the form Ax = b or $A^Tx = b$; the number is usually 4 or 5 and never more than 11. Each solution involves approximately $8n^2$ operations.

In practice the condition number estimator is very reliable, but it can underestimate the true condition number; see Section 15.3 of Higham (2002) for further details.

The real analogue of this routine is F07ABF (DGESVX).

9 Example

To solve the equations

$$AX = B$$
,

where A is the general matrix

$$A = \begin{pmatrix} -1.34 + 2.55i & 0.28 + 3.17i & -6.39 - 2.20i & 0.72 - 0.92i \\ -1.70 - 14.10i & 33.10 - 1.50i & -1.50 + 13.40i & 12.90 + 13.80i \\ -3.29 - 2.39i & -1.91 + 4.42i & -0.14 - 1.35i & 1.72 + 1.35i \\ 2.41 + 0.39i & -0.56 + 1.47i & -0.83 - 0.69i & -1.96 + 0.67i \end{pmatrix}$$

and

$$B = \begin{pmatrix} 26.26 + 51.78i & 31.32 - 6.70i \\ 64.30 - 86.80i & 158.60 - 14.20i \\ -5.75 + 25.31i & -2.15 + 30.19i \\ 1.16 + 2.57i & -2.56 + 7.55i \end{pmatrix}.$$

Error estimates for the solutions, information on scaling, an estimate of the reciprocal of the condition number of the scaled matrix A and an estimate of the reciprocal of the pivot growth factor for the factorization of A are also output.
