NAG Fortran Library Routine Document

F08KNF (ZGELSS)

Note: before using this routine, please read the Users' Note for your implementation to check the interpretation of *bold italicised* terms and other implementation-dependent details.

1 Purpose

F08KNF (ZGELSS) computes the minimum norm solution to a complex linear least-squares problem

$$\min_{x} \|b - Ax\|_2.$$

2 Specification

SUBROUTINE FO8KNF	(M, N, NRHS, A, LDA, B, LDB, S, RCOND, RANK, WORK,
1	LWORK, RWORK, INFO)
INTEGER	M, N, NRHS, LDA, LDB, RANK, LWORK, INFO
double precision	S(*), RCOND, RWORK(*)
complex*16	A(LDA,*), B(LDB,*), WORK(*)

The routine may be called by its LAPACK name zgelss.

3 Description

F08KNF (ZGELSS) uses the singular value decomposition (SVD) of A, where A is an m by n matrix which may be rank-deficient.

Several right-hand side vectors b and solution vectors x can be handled in a single call; they are stored as the columns of the m by r right-hand side matrix B and the n by r solution matrix X.

The effective rank of A is determined by treating as zero those singular values which are less than RCOND times the largest singular value.

5 Parameters

1: M – INTEGER

On entry: m, the number of rows of the matrix A. Constraint: $M \ge 0$.

2: N – INTEGER

On entry: n, the number of columns of the matrix A. Constraint: $N \ge 0$. Input

Input

3: NRHS – INTEGER

On entry: r, the number of right-hand sides, i.e., the number of columns of the matrices B and X. Constraint: NRHS ≥ 0 .

4: A(LDA,*) - complex*16 array

Note: the second dimension of the array A must be at least max(1, N).

On entry: the m by n matrix A.

On exit: the first $\min(m, n)$ rows of A are overwritten with its right singular vectors, stored rowwise.

5: LDA – INTEGER

On entry: the first dimension of the array A as declared in the (sub)program from which F08KNF (ZGELSS) is called.

Constraint: LDA \geq max(1, M).

6: B(LDB,*) - complex*16 array

Note: the second dimension of the array B must be at least max(1, NRHS).

On entry: the m by r right-hand side matrix B.

On exit: is overwritten by the n by r solution matrix X. If $m \ge n$ and RANK = n, the residual sum-of-squares for the solution in the *i*th column is given by the sum of squares of the modulus of elements $n + 1, \ldots, m$ in that column.

7: LDB – INTEGER

On entry: the first dimension of the array B as declared in the (sub)program from which F08KNF (ZGELSS) is called.

Constraint: LDB $\geq \max(1, M, N)$.

8: S(*) - double precision array

Note: the dimension of the array S must be at least max(1, min(M, N)).

On exit: the singular values of A in decreasing order.

9: RCOND – *double precision*

On entry: used to determine the effective rank of A. Singular values $S(i) \leq RCOND \times S(1)$ are treated as zero.

If RCOND < 0, *machine precision* is used instead.

10: RANK – INTEGER

On exit: the effective rank of A, i.e., the number of singular values which are greater than $RCOND \times S(1)$.

11: WORK(*) – *complex*16* array

Note: the dimension of the array WORK must be at least max(1, LWORK).

On exit: if INFO = 0, WORK(1) returns the optimal LWORK.

12: LWORK – INTEGER

On entry: the dimension of the array WORK as declared in the (sub)program from which F08KNF (ZGELSS) is called.

Input/Output

Input

Input/Output

Input

Input

Output

Workspace

Output

Input

Input

For good performance, LWORK should generally be larger. Consider increasing LWORK by at least $nb \times \min(M, N)$, where nb is the optimal block size.

If LWORK = -1, a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued.

Constraint: LWORK ≥ 1 and LWORK $\geq 2 \times \min(M, N) + \max(M, N, NRHS)$.

13: RWORK(*) – *double precision* array

Note: the dimension of the array RWORK must be at least $max(1, 5 \times min(M, N))$.

On exit: INFO = 0 unless the routine detects an error (see Section 6).

6 Error Indicators and Warnings

Errors or warnings detected by the routine:

$\mathrm{INFO} < 0$

If INFO = -i, the *i*th argument had an illegal value.

INFO > 0

The algorithm for computing the SVD failed to converge; if INFO = i, *i* off-diagonal elements of an intermediate bidiagonal form did not converge to zero.

7 Accuracy

See Section 4.5 of Anderson et al. (1999) for details.

8 Further Comments

The real analogue of this routine is F08KAF (DGELSS).

9 Example

To solve the linear least squares problem

$$\min \|b - Ax\|_2$$

for the solution, x, of minimum norm, where

$$A = \begin{pmatrix} 0.47 - 0.34i & -0.40 + 0.54i & 0.60 + 0.01i & 0.80 - 1.02i \\ -0.32 - 0.23i & -0.05 + 0.20i & -0.26 - 0.44i & -0.43 + 0.17i \\ 0.35 - 0.60i & -0.52 - 0.34i & 0.87 - 0.11i & -0.34 - 0.09i \\ 0.89 + 0.71i & -0.45 - 0.45i & -0.02 - 0.57i & 1.14 - 0.78i \\ -0.19 + 0.06i & 0.11 - 0.85i & 1.44 + 0.80i & 0.07 + 1.14i \end{pmatrix}$$

and

$$b = \begin{pmatrix} -1.08 - 2.59i \\ -2.61 - 1.49i \\ 3.13 - 3.61i \\ 7.33 - 8.01i \\ 9.12 + 7.63i \end{pmatrix}.$$

A tolerance of 0.01 is used to determine the effective rank of A.

Output

Workspace

Note that the block size (NB) of 64 assumed in this example is not realistic for such a small problem, but should be suitable for large problems.

9.1 Program Text

Note: the listing of the example program presented below uses *bold italicised* terms to denote precision-dependent details. Please read the Users' Note for your implementation to check the interpretation of these terms. As explained in the Essential Introduction to this manual, the results produced may not be identical for all implementations.
