# NAG Fortran Library Routine Document

# F08WPF (ZGGEVX)

**Note:** before using this routine, please read the Users' Note for your implementation to check the interpretation of **bold italicised** terms and other implementation-dependent details.

## 1    Purpose

F08WPF (ZGGEVX) computes for a pair of $n$ by $n$ complex nonsymmetric matrices $(A, B)$ the generalized eigenvalues, and optionally, the left and/or right generalized eigenvectors using the $QZ$ algorithm.

Optionally it also computes a balancing transformation to improve the conditioning of the eigenvalues and eigenvectors, reciprocal condition numbers for the eigenvalues, and reciprocal condition numbers for the right eigenvectors).

## 2    Specification

```
SUBROUTINE F08WPF (BALANC, JOBVL, JOBVR, SENSE, N, A, LDA, B, LDB,
1                  ALPHA, BETA, VL, LDVL, VR, LDVR, ILO, IHI, LSCALE,
2                  RSCALE, ABNRM, BBNRM, RCONDE, RCONDV, WORK, LWORK,
3                  RWORK, IWORK, BWORK, INFO)
 INTEGER          N, LDA, LDB, LDVL, LDVR, ILO, IHI, LWORK, IWORK(*),
1                  INFO
 double precision LSCALE(*), RSCALE(*), ABNRM, BBNRM, RCONDE(*),
1                  RCONDV(*), RWORK(*)
 complex*16       A(LDA,*), B(LDB,*), ALPHA(*), BETA(*), VL(LDVL,*),
1                  VR(LDVR,*), WORK(*)
 LOGICAL          BWORK(*)
 CHARACTER*1      BALANC, JOBVL, JOBVR, SENSE
```

The routine may be called by its LAPACK name *zggevx*.

## 3    Description

A generalized eigenvalue for a pair of matrices $(A, B)$ is a scalar $\lambda$ or a ratio $\alpha/\beta = \lambda$, such that $A - \lambda B$ is singular. It is usually represented as the pair $(\alpha, \beta)$, as there is a reasonable interpretation for $\beta = 0$, and even for both being zero.

The right generalized eigenvector $v_j$ corresponding to the generalized eigenvalue $\lambda_j$ of $(A, B)$ satisfies

$$Av_j = \lambda_j B v_j.$$

The left generalized eigenvector $u_j$ corresponding to the generalized eigenvalues $\lambda_j$ of $(A, B)$ satisfies

$$u_j^H A = \lambda_j u_j^H B,$$

where $u_j^H$ is the conjugate-transpose of $u_j$.

All the eigenvalues and, if required, all the eigenvectors of the complex generalized eigenproblem $Ax = \lambda Bx$ where $A$ and $B$ are complex, square matrices, are determined using the $QZ$ algorithm. The complex $QZ$ algorithm consists of three stages:

1.  $A$ is reduced to upper Hessenberg form (with real, non-negative sub-diagonal elements) and at the same time $B$ is reduced to upper triangular form.

2.  $A$ is further reduced to triangular form while the triangular form of $B$ is maintained and the diagonal elements of $B$ are made real and non-negative. This is the generalized Schur form of the pair $(A, B)$.

    This routine does not actually produce the eigenvalues $\lambda_j$, but instead returns $\alpha_j$ and $\beta_j$ such that

    $$\lambda_j = \alpha_j/\beta_j, \quad j = 1, 2, \ldots, n.$$

The division by $\beta_j$ becomes the responsibility of the user, since $\beta_j$ may be zero, indicating an infinite eigenvalue.

3. If the eigenvectors are required they are obtained from the triangular matrices and then transferred back into the original co-ordinate system.

For details of the balancing option, see Section 3 of the document for F08WVF (ZGGBAL).

## 5    Parameters

1:    BALANC – CHARACTER*1                                                                      *Input*

*On entry*: specifies the balance option to be performed:

    if BALANC = 'N', do not diagonally scale or permute;
    if BALANC = 'P', permute only;
    if BALANC = 'S', scale only;
    if BALANC = 'B', both permute and scale.

Computed reciprocal condition numbers will be for the matrices after permuting and/or balancing. Permuting does not change condition numbers (in exact arithmetic), but balancing does. In the absence of other information, BALANC = 'B' is recommended.

2:    JOBVL – CHARACTER*1                                                                        *Input*

*On entry*: if JOBVL = 'N', do not compute the left generalized eigenvectors.

If JOBVL = 'V', compute the left generalized eigenvectors.

3:    JOBVR – CHARACTER*1                                                                        *Input*

*On entry*: if JOBVR = 'N', do not compute the right generalized eigenvectors.

If JOBVR = 'V', compute the right generalized eigenvectors.

4:    SENSE – CHARACTER*1                                                                        *Input*

*On entry*: determines which reciprocal condition numbers are computed:

    if SENSE = 'N', none are computed;
    if SENSE = 'E', computed for eigenvalues only;
    if SENSE = 'V', computed for eigenvectors only;
    if SENSE = 'B', computed for eigenvalues and eigenvectors.

5:    N – INTEGER                                                                                 *Input*

*On entry*: $n$, the order of the matrix pencil $(A, B)$.

*Constraint*: N $\geq$ 0.

6:     A(LDA,∗) – ***complex\*16*** array             *Input/Output*

**Note**: the second dimension of the array A must be at least $\max(1, N)$.

*On entry*: the matrix $A$ in the pair $(A, B)$.

*On exit*: has been overwritten. If JOBVL = 'V' or JOBVR = 'V' or both, then $A$ contains the first part of the Schur form of the 'balanced' versions of the input $A$ and $B$.

7:     LDA – INTEGER             *Input*

*On entry*: the first dimension of the array A as declared in the (sub)program from which F08WPF (ZGGEVX) is called.

*Constraint*: $LDA \geq \max(1, N)$.

8:     B(LDB,∗) – ***complex\*16*** array             *Input/Output*

**Note**: the second dimension of the array B must be at least $\max(1, N)$.

*On entry*: the matrix $B$ in the pair $(A, B)$.

*On exit*: has been overwritten. If JOBVL = 'V' or JOBVR = 'V' or both, then B contains the second part of the real Schur form of the 'balanced' versions of the input $A$ and $B$.

9:     LDB – INTEGER             *Input*

*On entry*: the first dimension of the array B as declared in the (sub)program from which F08WPF (ZGGEVX) is called.

*Constraint*: $LDB \geq \max(1, N)$.

10:     ALPHA(∗) – ***complex\*16*** array             *Output*

**Note**: the dimension of the array ALPHA must be at least $\max(1, N)$.

*On exit*: see the description of BETA below.

11:     BETA(∗) – ***complex\*16*** array             *Output*

**Note**: the dimension of the array BETA must be at least $\max(1, N)$.

*On exit*: $\mathrm{ALPHA}(j)/\mathrm{BETA}(j)$, $j = 1, \ldots, N$, will be the generalized eigenvalues.

**Note:** the quotients $\mathrm{ALPHA}(j)/\mathrm{BETA}(j)$ may easily over- or underflow, and $\mathrm{BETA}(j)$ may even be zero. Thus, the user should avoid naively computing the ratio $\alpha_j/\beta_j$. However, $\max|\alpha_j|$ will be always less than and usually comparable with $\|A\|_2$ in magnitude, and $\max|\beta_j|$ always less than and usually comparable with $\|B\|_2$.

12:     VL(LDVL,∗) – ***complex\*16*** array             *Output*

**Note**: the second dimension of the array VL must be at least $\max(1, N)$.

*On exit*: if JOBVL = 'V', the left generalized eigenvectors $u_j$ are stored one after another in the columns of VL, in the same order as the corresponding eigenvalues. Each eigenvector will be scaled so the largest component will have |real part| + |imag. part| = 1.

If JOBVL = 'N', VL is not referenced.

13:     LDVL – INTEGER             *Input*

*On entry*: the first dimension of the array VL as declared in the (sub)program from which F08WPF (ZGGEVX) is called.

*Constraints*:

      if JOBVL = 'V', $LDVL \geq \max(1, N)$;
      $LDVL \geq 1$ otherwise.

14:    VR(LDVR,∗) – **complex*16** array                                                       *Output*

   **Note**: the second dimension of the array VR must be at least $\max(1, N)$.

   *On exit*: if JOBVR = 'V', the right generalized eigenvectors $v_j$ are stored one after another in the columns of VR, in the same order as the corresponding eigenvalues.

   Each eigenvector will be scaled so the largest component will have |real part| + |imag. part| = 1.

   If JOBVR = 'N', VR is not referenced.

15:    LDVR – INTEGER                                                                          *Input*

   *On entry*: the first dimension of the array VR as declared in the (sub)program from which F08WPF (ZGGEVX) is called.

   *Constraints*:

>       if JOBVR = 'V', LDVR $\geq \max(1, N)$;
>       LDVR $\geq 1$ otherwise.

16:    ILO – INTEGER                                                                          *Output*
17:    IHI – INTEGER                                                                          *Output*

   *On exit*: ILO and IHI are integer values such that $A(i, j) = 0$ and $B(i, j) = 0$ if $i > j$ and $j = 1, \ldots, ILO - 1$ or $i = IHI + 1, \ldots, N$.

   If BALANC = 'N' or 'S', ILO = 1 and IHI = N.

18:    LSCALE(∗) – **double precision** array                                                 *Output*

   **Note**: the dimension of the array LSCALE must be at least $\max(1, N)$.

   *On exit*: details of the permutations and scaling factors applied to the left side of $A$ and $B$.

   If $pl_j$ is the index of the row interchanged with row $j$, and $dl_j$ is the scaling factor applied to row $j$, then:

>       $LSCALE(j) = pl_j$ for $j = 1, \ldots, ILO - 1$;
>
>       $LSCALE = dl_j$ for $j = ILO, \ldots, IHI$;
>
>       $LSCALE = pl_j$ for $j = IHI + 1, \ldots, N$.

   The order in which the interchanges are made is N to $IHI + 1$, then 1 to $ILO - 1$.

19:    RSCALE(∗) – **double precision** array                                                 *Output*

   **Note**: the dimension of the array RSCALE must be at least $\max(1, N)$.

   *On exit*: details of the permutations and scaling factors applied to the right side of $A$ and $B$.

   If $pr_j$ is the index of the column interchanged with column $j$, and $dr_j$ is the scaling factor applied to column $j$, then:

>       $RSCALE(j) = pr_j$ for $j = 1, \ldots, ILO - 1$;
>       if $RSCALE = dr_j$ for $j = ILO, \ldots, IHI$;
>       if $RSCALE = pr_j$ for $j = IHI + 1, \ldots, N$.

   The order in which the interchanges are made is N to $IHI + 1$, then 1 to $ILO - 1$.

20:    ABNRM – **double precision**                                                           *Output*

   *On exit*: the 1-norm of the balanced matrix $A$.

21:    BBNRM – **double precision**                                                           *Output*

   *On exit*: the 1-norm of the balanced matrix $B$.

22:     RCONDE($*$) – ***double precision*** array                                    *Output*

Note: the dimension of the array RCONDE must be at least $\max(1, N)$.

*On exit*: if SENSE = 'E' or 'B', the reciprocal condition numbers of the eigenvalues, stored in consecutive elements of the array.

If SENSE = 'V', RCONDE is not referenced.

23:     RCONDV($*$) – ***double precision*** array                                    *Output*

Note: the dimension of the array RCONDV must be at least $\max(1, N)$.

*On exit*: if SENSE = 'V' or 'B', the estimated reciprocal condition numbers of the selected eigenvectors, stored in consecutive elements of the array.

If SENSE = 'E', RCONDV is not referenced.

24:     WORK($*$) – ***complex\*16*** array                                          *Workspace*

Note: the dimension of the array WORK must be at least $\max(1, \text{LWORK})$.

*On exit*: if INFO = 0, WORK(1) returns the optimal LWORK.

25:     LWORK – INTEGER                                                           *Input*

*On entry*: the dimension of the array WORK as declared in the (sub)program from which F08WPF (ZGGEVX) is called.

For good performance, LWORK must generally be larger than the minimum; increase workspace by, say, $nb \times N$, where $nb$ is the block size.

If LWORK $= -1$, a workspace query is assumed; the routine only calculates the optimal size of the WORK array, returns this value as the first entry of the WORK array, and no error message related to LWORK is issued.

*Constraints*:

        if SENSE = 'N' or 'E', LWORK $\geq \max(1, 3 \times N)$;
        if SENSE = 'V' or 'B', LWORK $\geq \max(1, 2 \times N \times N + 2 \times N)$;
        LWORK $\geq \max(1, 2 \times N)$ otherwise.

26:     RWORK($*$) – ***double precision*** array                                    *Workspace*

Note: the dimension of the array RWORK must be at least $\max(1, 6 \times N)$.

Real workspace.

27:     IWORK($*$) – INTEGER array                                                 *Workspace*

Note: the dimension of the array IWORK must be at least $\max(1, N + 2)$.

If SENSE = 'E', IWORK is not referenced.

28:     BWORK($*$) – LOGICAL array                                                 *Workspace*

Note: the dimension of the array BWORK must be at least $\max(1, N)$.

If SENSE = 'N', BWORK is not referenced.

29:     INFO – INTEGER                                                            *Output*

*On exit*: INFO = 0 unless the routine detects an error (see Section 6).

## 6    Error Indicators and Warnings

Errors or warnings detected by the routine:

INFO $< 0$

> If INFO $= -i$, the $i$th argument had an illegal value.

INFO $> 0$ and INFO $\leq$ N

> The $QZ$ iteration failed. No eigenvectors have been calculated, but ALPHA($j$) and BETA($j$) should be correct for $j = $ INFO $+ 1, \ldots,$ N.

INFO $>$ N

> $=$ N $+ 1$: other than $QZ$ iteration failed in F08XSF (ZHGEQZ).
>
> $=$ N $+ 2$: error return from F08YXF (ZTGEVC).

## 7    Accuracy

The computed eigenvalues and eigenvectors are exact for a nearby matrices $(A + E)$ and $(B + F)$, where

$$\|(E, F)\|_F = \mathrm{O}(\epsilon)\|(A, B)\|_F,$$

and $\epsilon$ is the **machine precision**.

An approximate error bound on the chordal distance between the $i$th computed generalized eigenvalue $w$ and the corresponding exact eigenvalue $\lambda$ is

$$\epsilon \times \|\mathrm{ABNRM}, \mathrm{BBNRM}\|_2 / \mathrm{RCONDE}(i).$$

An approximate error bound for the angle between the $i$th computed eigenvector VL($i$) or VR($i$) is given by

$$\epsilon \times \|\mathrm{ABNRM}, \mathrm{BBNRM}\|_2 / \mathrm{RCONDV}(i).$$

For further explanation of the reciprocal condition numbers RCONDE and RCONDV, see Section 4.11 of Anderson *et al.* (1999).

**Note:** interpretation of results obtained with the $QZ$ algorithm often requires a clear understanding of the effects of small changes in the original data. These effects are reviewed in Wilkinson (1979), in relation to the significance of small values of $\alpha_j$ and $\beta_j$. It should be noted that if $\alpha_j$ and $\beta_j$ are **both** small for any $j$, it may be that no reliance can be placed on **any** of the computed eigenvalues $\lambda_i = \alpha_i/\beta_i$. The user is recommended to study Wilkinson (1979) and, if in difficulty, to seek expert advice on determining the sensitivity of the eigenvalues to perturbations in the data.

## 8    Further Comments

The total number of floating-point operations is proportional to $n^3$.

The real analogue of this routine is F08WBF (DGGEVX).

## 9 Example

To find all the eigenvalues and right eigenvectors of the matrix pair $(A, B)$, where

$$A = \begin{pmatrix} -21.10 - 22.50i & 53.50 - 50.50i & -34.50 + 127.50i & 7.50 + 0.50i \\ -0.46 - 7.78i & -3.50 - 37.50i & -15.50 + 58.50i & -10.50 - 1.50i \\ 4.30 - 5.50i & 39.70 - 17.10i & -68.50 + 12.50i & -7.50 - 3.50i \\ 5.50 + 4.40i & 14.40 + 43.30i & -32.50 - 46.00i & -19.00 - 32.50i \end{pmatrix}$$

and

$$B = \begin{pmatrix} 1.00 - 5.00i & 1.60 + 1.20i & -3.00 + 0.00i & 0.00 - 1.00i \\ 0.80 - 0.60i & 3.00 - 5.00i & -4.00 + 3.00i & -2.40 - 3.20i \\ 1.00 + 0.00i & 2.40 + 1.80i & -4.00 - 5.00i & 0.00 - 3.00i \\ 0.00 + 1.00i & -1.80 + 2.40i & 0.00 - 4.00i & 4.00 - 5.00i \end{pmatrix},$$

together with estimates of the condition number and forward error bounds for each eigenvalue and eigenvector. The option to balance the matrix pair is used.

Note that the block size (NB) of 64 assumed in this example is not realistic for such a small problem, but should be suitable for large problems.

### 9.1 Program Text

**Note:** the listing of the example program presented below uses **bold italicised** terms to denote precision-dependent details. Please read the Users' Note for your implementation to check the interpretation of these terms. As explained in the Essential Introduction to this manual, the results produced may not be identical for all implementations.
