

NAG Fortran Library Routine Document

F12ANF

Note: before using this routine, please read the Users' Note for your implementation to check the interpretation of ***bold italicised*** terms and other implementation-dependent details.

1 Purpose

F12ANF is a setup routine in a suite of routines consisting of F12ANF, F12APF, F12AQF, F12ARF and F12ASF. It is used to find some of the eigenvalues (and optionally the corresponding eigenvectors) of a standard or generalized eigenvalue problem defined by complex nonsymmetric matrices.

The suite of routines is suitable for the solution of large sparse, standard or generalized, nonsymmetric complex eigenproblems where only a few eigenvalues from a selected range of the spectrum are required.

2 Specification

```
SUBROUTINE F12ANF (N, NEV, NCV, ICOMM, LICCOMM, COMM, LCOMM, IFAIL)
INTEGER           N, NEV, NCV, ICOMM(*), LICCOMM, LCOMM, IFAIL
complex*16      COMM(*)
```

3 Description

The suite of routines is designed to calculate some of the eigenvalues, λ , (and optionally the corresponding eigenvectors, x) of a standard complex eigenvalue problem $Ax = \lambda x$, or of a generalized complex eigenvalue problem $Ax = \lambda Bx$ of order n , where n is large and the coefficient matrices A and B are sparse, complex and nonsymmetric. The suite can also be used to find selected eigenvalues/eigenvectors of smaller scale dense, complex and nonsymmetric problems.

F12ANF is a setup routine which must be called before F12APF, the reverse communication iterative solver, and before F12ARF, the options setting routine. F12AQF, is a post-processing routine that must be called following a successful final exit from F12APF, while F12ASF can be used to return additional monitoring information during the computation.

This setup routine initializes the communication arrays, sets (to their default values) all options that can be set by the user via the option setting routine F12ARF, and checks that the lengths of the communication arrays as passed by the user are of sufficient length. For details of the options available and how to set them see Section 10.2 of the document for F12ARF.

5 Parameters

1: N – INTEGER *Input*

On entry: the order of the matrix A (and the order of the matrix B for the generalized problem) that defines the eigenvalue problem.

Constraint: $N > 0$.

2: NEV – INTEGER *Input*

On entry: the number of eigenvalues to be computed.

Constraint: $0 < \text{NEV} < N - 1$.

3: NCV – INTEGER *Input*

On entry: the number of Arnoldi basis vectors to use during the computation.

At present there is no a-priori analysis to guide the selection of NCV relative to NEV. However, it is recommended that $\text{NCV} \geq 2 \times \text{NEV} + 1$. If many problems of the same type are to be solved, you should experiment with increasing NCV while keeping NEV fixed for a given test problem. This will usually decrease the required number of matrix-vector operations but it also increases the work and storage required to maintain the orthogonal basis vectors. The optimal ‘cross-over’ with respect to CPU time is problem dependent and must be determined empirically.

Constraint: $\text{NEV} + 1 < \text{NCV} \leq N$.

4: ICOMM(*) – INTEGER array Communication Array
Input

On entry: the dimension of the array ICOMM as declared in the (sub)program from which F12ANF is called.

If LICCOMM = -1 , a workspace query is assumed and the routine only calculates the required dimension of ICOMM, which it returns in ICOMM(1).

Constraint: LICCOMM ≥ 140 .

6: COMM(*) – **complex*16** array Communication Array
Input

On entry: the dimension of the array COMM as declared in the (sub)program from which F12ANF is called.

If LCOMM = -1 , a workspace query is assumed and the routine only calculates the required dimension of COMM, which it returns in COMM(1).

Constraint: LCOMM $\geq 3 \times N + 3 \times \text{NCV} \times \text{NCV} + 5 \times \text{NCV} + 60$.

8: IFAIL – INTEGER *Input/Output*

On entry: IFAIL must be set to 0, -1 or 1. Users who are unfamiliar with this parameter should refer to Chapter P01 for details.

On exit: IFAIL = 0 unless the routine detects an error (see Section 6).

For environments where it might be inappropriate to halt program execution when an error is detected, the value -1 or 1 is recommended. If the output of error messages is undesirable, then the value 1 is recommended. Otherwise, for users not familiar with this parameter the recommended value is 0. **When the value -1 or 1 is used it is essential to test the value of IFAIL on exit.**

6 Error Indicators and Warnings

If on entry IFAIL = 0 or -1, explanatory error messages are output on the current error message unit (as defined by X04AAF).

Errors or warnings detected by the routine:

IFAIL = 1

On entry, $N \leq 0$.

IFAIL = 2

On entry, $NEV \leq 0$.

IFAIL = 3

On entry, $NCV < NEV + 2$ or $NCV > N$.

IFAIL = 4

On entry, LICCOMM < 140 and LICCOMM $\neq -1$.

IFAIL = 5

On entry, LCOMM < $3 \times N + 3 \times NCV \times NCV + 5 \times NCV + 60$ and LCOMM $\neq -1$.

7 Accuracy

Not applicable.

8 Further Comments

None.

9 Example

The example solves $Ax = \lambda x$ in regular mode, where A is obtained from the standard central difference discretization of the convection-diffusion operator $\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} + \rho \frac{\partial u}{\partial x}$ on the unit square, with zero Dirichlet boundary conditions. The eigenvalues of largest magnitude are found.
