

NAG Fortran Library Routine Document

G02ECF

Note: before using this routine, please read the Users' Note for your implementation to check the interpretation of *bold italicised* terms and other implementation-dependent details.

1 Purpose

G02ECF calculates R^2 and C_p -values from the residual sums of squares for a series of linear regression models.

2 Specification

```

SUBROUTINE G02ECF(MEAN, N, SIGSQ, TSS, NMOD, NTERMS, RSS, RSQ, CP,
1                IFAIL)
  INTEGER          N, NMOD, NTERMS(NMOD), IFAIL
  real           SIGSQ, TSS, RSS(NMOD), RSQ(NMOD), CP(NMOD)
  CHARACTER*1     MEAN

```

3 Description

When selecting a linear regression model for a set of n observations a balance has to be found between the number of independent variables in the model and fit as measured by the residual sum of squares. The more variables included the smaller will be the residual sum of squares. Two statistics can help in selecting the best model.

- (a) R^2 represents the proportion of variation in the dependent variable that is explained by the independent variables.

$$R^2 = \frac{\text{Regression Sum of Squares}}{\text{Total Sum of Squares}},$$

where Total sum of squares = $TSS = \sum (y - \bar{y})^2$ (if mean is fitted, otherwise $TSS = \sum y^2$) and
 Regression sum of squares = $\text{RegSS} = TSS - \text{RSS}$, where
 $\text{RSS} = \text{residual sum of squares} = \sum (y - \hat{y})^2$.

The R^2 -values can be examined to find a model with a high R^2 -value but with small number of independent variables.

- (b) C_p statistic.

$$C_p = \frac{\text{RSS}}{\hat{\sigma}^2} - (n - 2p),$$

where p is the number of parameters (including the mean) in the model and $\hat{\sigma}^2$ is an estimate of the true variance of the errors. This can often be obtained from fitting the full model.

A well fitting model will have $C_p \simeq p$. C_p is often plotted against p to see which models are closest to the $C_p = p$ line.

G02ECF may be called after G02EAF which calculates the residual sums of squares for all possible linear regression models.

5 Parameters

- 1: MEAN – CHARACTER*1 *Input*
On entry: indicates if a mean term is to be included.
 If MEAN = 'M' (Mean), a mean term, intercept, has been included in the model.
 If MEAN = 'Z' (Zero), the model passes through the origin, zero-point.
Constraint: MEAN = 'M' or 'Z'.
- 2: N – INTEGER *Input*
On entry: the number of observations used in the regression model, n .
Constraint: N must be greater than $2 \times p_{\max}$, where p_{\max} is the largest number of independent variables fitted (including the mean if fitted).
- 3: SIGSQ – *real* *Input*
On entry: the best estimate of true variance of the errors, $\hat{\sigma}^2$.
Constraint: SIGSQ > 0.0.
- 4: TSS – *real* *Input*
On entry: the total sum of squares for the regression model.
Constraint: TSS > 0.0.
- 5: NMOD – INTEGER *Input*
On entry: the number of regression models.
Constraint: NMOD > 0.
- 6: NTERMS(NMOD) – INTEGER array *Input*
On entry: NTERMS(i) must contain the number of independent variables (not counting the mean) fitted to the i th model, for $i = 1, 2, \dots, \text{NMOD}$.
- 7: RSS(NMOD) – *real* array *Input*
On entry: RSS(i) must contain the residual sum of squares for the i th model.
Constraint: RSS(i) \leq TSS, for $i = 1, 2, \dots, \text{NMOD}$.
- 8: RSQ(NMOD) – *real* array *Output*
On exit: RSQ(i) contains the R^2 -value for the i th model, for $i = 1, 2, \dots, \text{NMOD}$.
- 9: CP(NMOD) – *real* array *Output*
On exit: CP(i) contains the C_p -value for the i th model, for $i = 1, 2, \dots, \text{NMOD}$.
- 10: IFAIL – INTEGER *Input/Output*
On entry: IFAIL must be set to 0, -1 or 1. Users who are unfamiliar with this parameter should refer to Chapter P01 for details.
On exit: IFAIL = 0 unless the routine detects an error (see Section 6).
 For environments where it might be inappropriate to halt program execution when an error is detected, the value -1 or 1 is recommended. If the output of error messages is undesirable, then the value 1 is recommended. Otherwise, for users not familiar with this parameter the recommended value is 0. **When the value -1 or 1 is used it is essential to test the value of IFAIL on exit.**

6 Error Indicators and Warnings

If on entry $IFAIL = 0$ or -1 , explanatory error messages are output on the current error message unit (as defined by X04AAF).

Errors or warnings detected by the routine:

$IFAIL = 1$

On entry, $NMOD < 1$,
 or $SIGSQ \leq 0.0$,
 or $TSS \leq 0.0$.
 or $MEAN \neq 'M'$ or $'Z'$.

$IFAIL = 2$

On entry, the number of parameters for a model is too large for the number of observations, i.e., $2 \times p \geq n$.

$IFAIL = 3$

On entry, $RSS(i) > TSS$, for some $i = 1, 2, \dots, NMOD$.

$IFAIL = 4$

A value of C_p is less than 0.0. This may occur if $SIGSQ$ is too large or if RSS , N or IP are incorrect.

7 Accuracy

Accuracy is sufficient for all practical purposes.

8 Further Comments

None.

9 Example

The data, from an oxygen uptake experiment, is given by Weisberg (1985). The independent and dependent variables are read and the residual sums of squares for all possible models computed using G02EAF. The values of R^2 and C_p are then computed and printed along with the names of variables in the models.

9.1 Program Text

Note: the listing of the example program presented below uses *bold italicised* terms to denote precision-dependent details. Please read the Users' Note for your implementation to check the interpretation of these terms. As explained in the Essential Introduction to this manual, the results produced may not be identical for all implementations.
